Check-boxes reserved for designating States (for the purposes of a national patent) which have become party to the PCT after issuance of this sheet:

- ☐
- ☐
- ☐
- ☐

In addition to the designations made above, the applicant also makes under Rule 4.9(b) all designations which would be permitted under the PCT except the designation(s) of The applicant declares that those additional designations are subject to confirmation and that any designation which is not confirmed before the expiration of 15 months from the priority date is to be regarded as withdrawn by the applicant at the expiration of that time limit. (Confirmation of a designation consists of the filing of a notice specifying that designation and the payment of the designation and confirmation fees. Confirmation must reach the receiving Office within the 15-month time limit.)

THIS PAGE BLANK (USPTO)

Box No. VI PRIORITY CLAIM

Further priority claims are indicated in the Supplemental Box ☐

The priority of the following earlier application(s) is hereby claimed:

Country (in which, or for which, the application was filed)	Filing Date (day/month/year)	Application No.	Office of filing (only for regional or international application)
item (1)			
item (2)			
item (3)			

Mark the following check-box if the certified copy of the earlier application is to be issued by the Office which for the purposes of the present international application is the receiving Office (a fee may be required):

☐ The receiving Office is hereby requested to prepare and transmit to the International Bureau a certified copy of the earlier application(s) identified above as item(s): _____

Box No. VII INTERNATIONAL SEARCHING AUTHORITY

Choice of International Searching Authority (ISA) (If two or more International Searching Authorities are competent to carry out the international search, indicate the Authority chosen; the two-letter code may be used):

ISA/ EPO

Earlier search Fill in where a search (international, international-type or other) by the International Searching Authority has already been carried out or requested and the authority is not requested to base the international search, to the extent possible, on the results of that earlier search. Identify such search or request either by reference to the relevant application (or the translation thereof) or by reference to the search request:

Country (or regional Office):

Date (day/month/year):

Number:

Box No. VIII CHECK LIST

This international application contains the following number of sheets:

1. request : 4 sheets
 2. description : 66 sheets
 3. claims : 8 sheets
 4. abstract : 1 sheets
 5. drawings : 34 sheets

Total: 113 sheets

This international application is accompanied by the item(s) marked below:

1. ☐ separate signed power of attorney
 2. ☐ copy of general power of attorney
 3. ☐ statement explaining lack of signature
 4. ☐ priority document(s) identified in Box No. VI as item(s): _____
 5. ☒ fee calculation sheet
 6. ☐ separate indications, deposited microorganisms
 7. ☐ nucleotide and/or amino acid sequence listing (diskette)
 8. ☐ other (specify): _____

Figure No. 1 of the drawings (if any) should accompany the abstract when it is published.

Box No. IX SIGNATURE OF APPLICANT OR AGENT

Next to each signature, indicate the name of the person signing and the capacity in which the person signs (if such capacity is not obvious from reading the request).

Danielle J. Miquel

For receiving Office use only

1. Date of the actual receipt of the purported international application:	2. Drawings: <input type="checkbox"/> received: <input type="checkbox"/> not received.
3. Corrected date of actual receipt due to later but timely received papers or drawings completing the purported international application:	
4. Date of timely receipt of the required corrections under PCT Article 11(2):	
5. International Searching Authority specified by the applicant: <u>ISA/</u>	
6. <input type="checkbox"/> Transmittal of search copy delayed until search fee is paid.	

For International Bureau use only

Date of receipt of the record copy by the International Bureau:

INVITATION TO PAY ADDITIONAL FEES

(PCT Article 17(3)(a) and Rule 40.1)

Date of mailing (day/month/year) 03/12/1998	
Applicant's or agent's file reference 4-013PCT	PAYMENT DUE within 45 days /days from the above date of mailing
International application No. PCT/US 98/ 07806	International filing date (day/month/year) 21/04/1998
Applicant UNIVERSITE LAVAL et al.	

1. This International Searching Authority

- (i) considers that there are 2 (number of) inventions claimed in the international application covered by the claims indicated ~~below~~ on the extra sheet:

and it considers that the international application does not comply with the requirements of unity of invention (Rules 13.1, 13.2 and 13.3) for the reasons indicated ~~below~~ on the extra sheet:

- (ii) ☒ has carried out a partial international search (see Annex) ☐ will establish the international search report on those parts of the international application which relate to the invention first mentioned in claims Nos.:

1-23, 27-31

- (iii) will establish the international search report on the other parts of the international application only if, and to the extent to which, additional fees are paid

2. The applicant is hereby **invited**, within the time limit indicated above, to pay the amount indicated below:

DEM 2200 x 1 = DEM 2200
Fee per additional invention number of additional inventions total amount of additional fees

The applicant is informed that, according to Rule 40.2(c), the payment of any additional fee may be made under protest, i.e., a reasoned statement to the effect that the international application complies with the requirement of unity of invention or that the amount of the required additional fee is excessive.

3. ☒ Claim(s) Nos. 16-20 have been found to be unsearchable under Article 17(2)(b) because of defects under Article 17(2)(a) and therefore have not been included with any invention.

THIS PAGE BLANK (USPTO)

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-23,27-31

Polyamine derivatives having an amide group as well as their use

2. Claims: 24-26,32-43

Polyamine derivatives with linker having no amide group

The problem underlying the application is the provision of competitive inhibitors of polyamine transport.

The proposed solution is the provision of synthetic derivatives of original polyamines comprising an amide group or a synthetic derivative of polyamine according to the formulae of claims 24, 32, 34 or 38 respectively, comprising no amide group.

A priori the common concept underlying the present application could be seen in the provision of synthetic derivatives of polyamines useful as competitive inhibitors of polyamine transport.

However, the Journal of Biological Chemistry, vol. 271, N. 44, 1996, pp. 27556-27563 (D1), see for instance pages 27556 and 27559 already refers to such synthetic derivative of an original polyamine as specific inhibitors of polyamine transport.

Consequently, the apriori common concept is not novel.

The problem to be solved is therefore the provision of further synthetic derivatives of original polyamines.

The solutions proposed are:

1. Polyamines derivatives having an amide group

2. polyamines derivatives with linker and having no amide group

No other features which could play the role of special technical features, linking the two solutions within the meaning of rule 13.2 PCT, can be distinguished. Therefore, no single inventive concept underlying a unique invention can be distinguished.

Consequently the requirements of Art. 13.1 are not met and there is a lack of non-unity a posteriori.

The different inventions not belonging to a common inventive concept are formulated as the different subjects on the communication pursuant to Article 17(3)(a) PCT.

Two different non-unity objects can be distinguished, each characterised by special technical features, these different inventions have been regrouped into a minimal number of subjects.

THIS PAGE BLANK (USPTO)

INVITATION TO PAY ADDITIONAL FEES

International application No.

PCT/US 98/07806

- 1) Polyamine derivatives having a amide group as well as their use.
- 2) Polyamine derivatives with linker and having no amide group.

The search has been carried out only with respect to the first subject. Searching the invention of group 2 would have caused major additional searching efforts.
It is also stressed that according to the result of the search of the second object an objection of lack of unity can be arised.

THIS PAGE BLANK (USPTO)

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 206

Although claims 16-20 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

Further defect(s) under Article 17(2)(a):

Claims Nos.: 16-20

Rule 39.1(iv) PCT - Method for treatment of the human or animal body by therapy

THIS PAGE BLANK (USPTO)

1. The present communication is an Annex to the invitation to pay additional fees (Form PCT/ISA/206). It shows the results of the international search established on the parts of the international application which relate to the invention first mentioned in claims Nos.:
1-23, 27-31
2. This communication is not the international search report which will be established according to Article 18 and Rule 43.
3. If the applicant does not pay any additional search fees, the information appearing in this communication will be considered as the result of the international search and will be included as such in the international search report.
4. If the applicant pays additional fees, the international search report will contain both the information appearing in this communication and the results of the international search on other parts of the international application for which such fees will have been paid.

Rule 40

Lack of Unity of Invention (International Search)

40.1 *Invitation to Pay*

The invitation to pay additional fees provided for in Article 17(3)(a) shall specify the reasons for which the international application is not considered as complying with the requirement of unity of invention and shall indicate the amount to be paid.

40.2 *Additional Fees*

(a) The amount of the additional fee due for searching under Article 17(3)(a) shall be determined by the competent International Searching Authority.

(b) The additional fee due for searching under Article 17(3)(a) shall be payable direct to the International Searching Authority.

(c) Any applicant may pay the additional fee under protest, that is, accompanied by a reasoned statement to the effect that the international application complies with the requirement of unity of invention or that the amount of the required additional fee is excessive. Such protest shall be examined by a three-member board or other special instance of the International Searching Authority or any competent higher authority, which, to the extent that it finds the protest justified, shall order the total or partial reimbursement to the applicant of the additional fee. On the request of the applicant, the text of both the protest and the decision thereon shall be notified to the designated Offices together with the international search report. The applicant shall submit any translation thereof with the furnishing of the translation of the international application required under Article 22.

(d) The three-member board, special instance or competent higher authority, referred to in paragraph (c), shall not comprise any person who made the decision which is the subject of the protest.

(e) Where the applicant has, under paragraph (c), paid an additional fee under protest, the International Searching Authority may, after a prior review of the justification for the invitation to pay an additional fee, require that the applicant pay a fee for the examination of the protest ("protest fee"). The protest fee shall be paid within one month from the date of the notification to the applicant of the result of the review. If the protest fee is not so paid, the protest shall be considered withdrawn. The protest fee shall be refunded to the applicant where the three-member board, special instance or higher authority referred to in paragraph (c) finds that the protest was entirely justified.

40.3 *Time Limit*

The time limit provided for in Article 17(3)(a) shall be fixed, in each case, according to the circumstances of the case, by the International Searching Authority; it shall not be shorter than 15 or 30 days, respectively, depending on whether the applicant's address is in the same country as or in a different country from that in which the International Searching Authority is located, and it shall not be longer than 45 days, from the date of the invitation.

INTERNATIONAL SEARCH REPORT

(PCT Article 18 and Rules 43 and 44)

Applicant's or agent's file reference 4-013PCT	FOR FURTHER ACTION see Notification of Transmittal of International Search Report (Form PCT/ISA/220) as well as, where applicable, item 5 below.	
International application No. PCT/US 98/ 07806	International filing date (day/month/year) 21/04/1998	(Earliest) Priority Date (day/month/year)
Applicant UNIVERSITE LAVAL et al.		

This International Search Report has been prepared by this International Searching Authority and is transmitted to the applicant according to Article 18. A copy is being transmitted to the International Bureau.

This International Search Report consists of a total of 5 sheets.
☒ It is also accompanied by a copy of each prior art document cited in this report.

1. ☒ **Certain claims were found unsearchable** (see Box I).

2. ☒ **Unity of invention is lacking** (see Box II).

3. ☐ The international application contains disclosure of a **nucleotide and/or amino acid sequence listing** and the international search was carried out on the basis of the sequence listing

☐ filed with the international application.
☐ furnished by the applicant separately from the international application,
 ☐ but not accompanied by a statement to the effect that it did not include matter going beyond the disclosure in the international application as filed.

☐ Transcribed by this Authority

4. With regard to the **title**, ☒ the text is approved as submitted by the applicant.
 ☐ the text has been established by this Authority to read as follows:

5. With regard to the **abstract**,

☒ the text is approved as submitted by the applicant.
☐ the text has been established, according to Rule 38.2(b), by this Authority as it appears in Box III. The applicant may, within one month from the date of mailing of this International Search Report, submit comments to this Authority.

6. The figure of the **drawings** to be published with the abstract is:
 Figure No. 1 ☒ as suggested by the applicant. ☐ None of the figures.
 ☐ because the applicant failed to suggest a figure.
 ☐ because this figure better characterizes the invention.

Box I Observation where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 16-20
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claim(s) 16-20
is(are) directed to a method of treatment of the human/animal
body, the search has been carried out and based on the alleged
effects of the compound/composition.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such
an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see further information sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all
searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment
of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report
covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is
restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-23, 27-31

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/

Annex 1

Reason for incomplete search of following claims:

1. Claims 1- 5,21- 23:
A compound cannot be defined by its intended biological effect such as "inhibiting the cellular uptake of a polyamine".
2. Claims 6,7- 12 (see also page 6):
The general formula contains C- atoms having 5 and 6 bonds, C- atoms having only 2 or 3 bonds, N- atoms having 5 bonds.
 R^1, R^2, R^3 cannot be found in the given formula.
The definition for "S", namely "a molecule which cannot be captured by said natural polyamine transporter" is unclear.
Since "S" is the chemical symbol for sulfur it should be replaced.
3. Claims 16- 20:
These claims are directed to a method of treatment or diagnosis of the human body (R.39(1)iv PCT).
Claim 18: there is no "inhibitor of a polyamine synthesis" mentioned in claim 16.
4. Claim 24- 25:
The general formula contains N- atoms having 4 bonds and a C- atom having 2 bonds.
The attachment point of the linker "L" is not clear.
The definition of "L" is unclear since only a biological function is mentioned.
The meaning of "L- H₃" is unclear.
Only one of R^1 or R^2 and R^{11} or R^{12} is defined as being "methyl". However, there is no definition given for the other substituents which can thus be anything.
5. Claim 26:
According to claim 24 at least **two** methyl- groups are present (see def. of R^1, R^2, R^{11}, R^{12}), whereas according to claim 26 at least **one** methyl- group must be present.
6. Claim 32- 33:
The given "structure 1" is different from "structure 1" as shown on page 40.
There is no substituent " R_3 " in the given formula.
"L" is not defined.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/

"z" is not defined.

The definition of "w" is obscure, the definition of "x" appears twice.

"y" does not appear in the given formula.

The definition of "R₂" in claim 33 is unclear.

7. Claim 34

"L" is not defined.

"z" is not defined.

The definition of "w" is obscure, the definition of "x" appears twice.

There is no index "y" in the given formula.

8. Claim 36

L' is not defined.

"z" and "y" are not defined individually.

The definition of "w" is obscure, the definition of "x" appears twice.

R₃ cannot be "alkyl", "amide", "ether", "thioether".

9. "DEASC" as shown in figure 1 is different from the formula on page7, line 8 (- NH₂- group is missing).

10. Claims 13- 15:

The nomenclature of "MESC", "DESC", "DEASC" does not correspond to the well- recognized nomenclature in chemistry.

(54) Title: POLYAMINE TRANSPORT INHIBITORS

(57) Abstract

The present invention describes the design, synthesis and therapeutic use of a variety of novel inhibitors of polyamine transport. The main feature of this class of transport inhibitors is to incorporate a linker or side chain that prevents the uptake of polyamines and helps to conjugate polyamine analogs to form dimers with high inhibitory potency against polyamine uptake. These new compounds incorporate features that are designed to maximize their chemical and metabolic stability and their ability to bind to the polyamine transporter, and to minimize their toxicity by preventing their absorption by the cells. The purpose of such inhibitors is to prevent the uptake or salvaging of circulating polyamines by rapidly proliferating cells such as tumor cells, in order to potentiate the effect of therapeutic inhibitors of polyamine biosynthesis such as alpha-difluoromethylornithine.

THIS PAGE BLANK (USPTO)

POLYAMINE TRANSPORT INHIBITORS

5

FIELD OF THE INVENTION

The present invention relates to a novel class of competitive inhibitors of natural polyamine transport in mammalian cells. The present invention is more particularly directed to low molecular weight, high-affinity, specific, impermeant, pure antagonists of polyamine transport of a structure different to that of endogenous polyamines. The novel inhibitors of the present invention exhibit an effect on cultured tumor cells essentially cytostatic, with minor non-specific effects. The present invention is also directed to the use of such novel inhibitors of polyamine transport to evaluate the antitumor efficacy of polyamine depletion strategies with minimal systemic cytotoxic effects or to control and treat disorders involving unrestrained cell proliferation and/or cell differentiation wherein polyamine transport is required.

20

BACKGROUND OF THE INVENTION

Natural polyamines such as putrescine (1,4-butane-diamine), spermidine (*N*-3[-aminopropyl]-1,4-diaminobutane) and spermine (*N,N'*-bis-[3-aminopropyl]-1,4-butane-diamine) play essential roles in the control of macromolecular synthesis and growth processes in eukaryotic cells. Cells maintain appropriate polyamine concentrations principally by *de novo* synthesis from amino acids wherein ornithine decarboxylase catalyzes conversion of ornithine to putrescine, which is then converted to spermidine and spermine. Most tissues also possess a specific plasma membrane transport system allowing for utilization of plasma sources of polyamines.

30

Inhibitors of polyamine biosynthesis such as α -difluoromethylornithine (DFMO), which inhibits ornithine decarboxylase, cause an extensive depletion of polyamines followed by growth arrest in virtually all known mammalian cell types *in vitro*. Since tissues such as tumor cells and other transformed or rapidly proliferating cells exhibit a

THIS PAGE BLANK (USPTO)

tissues such as tumor cells and other transformed or rapidly proliferating cells exhibit a high demand for polyamines, these properties have encouraged an extensive assessment of such inhibitors for the treatment of proliferative diseases, including several types of tumors, in experimental models and in clinical trials. Unfortunately, the antitumor efficacy of such inhibitors *in vivo* has been disappointing. The failure of DFMO to halt tumor growth in animal models has been clearly correlated with the elevated polyamine transport activity found in transformed cells. Indeed, decontamination of the gastrointestinal tract, which is the main vector of circulating polyamines through bacterial microflora activity, along with a polyamine-free diet, markedly potentiate the *in vivo* efficacy of DFMO against tumor progression. Moreover, mutant mouse leukemia cells deficient in polyamine transport are much more susceptible than the parental strain to growth inhibition by DFMO treatment in host animals. Besides, growth inhibition associated with DFMO-induced polyamine depletion in ZR-75-1 human breast cancer cells can be completely reversed by concentrations of spermidine as low as 300 nM, i.e., such as those found in human plasma (Moulinoux, J.-P., Quemener, V., and Khan, N.A. 1991. *Cell. Mol. Biol.* 37: 773-783; Scalabrino, G. and Ferioli, M.E. 1981. *Adv. Cancer Res.* 36: 1-102; Bachrach, U., 1989. in *The Physiology of Polyamines* (Bachrach, U. and Heimer, Y.M., eds.) Vol. II, pp. 235-249, 2 vols, CRC Press, Boca Raton, FL). The striking efficiency of the transport system to salvage exogenous polyamines in DFMO-treated cells owes to its upregulation consecutive to polyamine depletion (Seiler, N. and Dezeure, F. 1980. *Int. J. Biochem.* 22: 211-218; Byers, T.L. and Pegg, A.E. 1990. *J. Cell Physiol.* 143: 460-467; Lessard, M., Zhao, C., Singh, S.M. and Poulin, R. 1995. *J. Biol. Chem.* 270: 1685-1694; Kakinuma, Y., Hoshino, K., and Igarashi, K. 1988. *Eur. J. Biochem.* 176: 409-414). These data reinforce the view that cellular import of exogenous polyamines is the main factor limiting the efficacy of DFMO and other polyamine biosynthesis inhibitors as antitumor agents *in vivo* (Sarhan, S. Knödgen, B., and Seiler, N. 1989. *Anticancer Res.* 9: 215-224; Hessels, J., Kingma, A.W., Ferwerda, H., Keij, J., Van der Berg, G.A., and Muskiet, F.A.J. 1989. *Int. J. Cancer* 43: 115-1166; Ask, A., Persson, L. and Heby, O. 1992. *Cancer Lett.* 66: 29-34; Seiler, N., Sarhan, S., Grauffel, C., Jones, R., Knödgen, B. and Moulinoux, J.-P. 1990. *Cancer Res.* 50: 5077-5083; Persson, L., Holm, I., Ask, A. and Heby, O. 1988. *Cancer Res.* 48: 4807-4811).

THIS PAGE BLANK (USPTO)

Depletion of intracellular polyamines in tumor cells is thus a well-known strategy in anticancer therapies. However, it is now of common knowledge that depleting intracellular polyamines generally enhances polyamine uptake. To date, molecular information on the carrier molecules of the mammalian polyamine transport system is still unavailable. A few attempts have been made previously to design specific inhibitors of polyamine transport. Based on the finding that paraquat (4,4'-bipyridine) is a substrate of the putrescine transport system (Smith, L.L. and Wyatt, I. 1981. *Biochem. Pharmacol.* 20, 1053-1058; Rannels, D.E., Pegg, A.E., Clark, R.S. and Addison, J.L. 1985. *Am. J. Physiol.* 249, E506-E513), a series of polypyridinium salts, including compounds with a low K_i against putrescine uptake and low acute toxicity for mammalian cells have been synthesized (Minchin, R.F., Martin, R.L., Summers, L.A. and Ilett, K.F. 1989. *Biochem. J.* 262, 391-395). However, it is unclear whether such compounds can efficiently inhibit polyamine transport or are accumulated intracellularly. A number of polyamine analogs are effective competitors of polyamine uptake while being themselves substrates for transport (Seiler, N. and Dezeure, F., 1990. *Int. J. Biochem. Cell. Biol.* 27: 425-442; Bergeron, R.J., and Seligsohn, H.W. (1986) *Bioinorg. Chem.* 14: 345-355; Porter, C.W., Bergeron, R.J. and Stolowich, N.J. 1982. *Cancer Res.* 42: 4072-4078; Porter, C.W., Basu, H.S., Feuerstein, B.G., Deen, D.F., Lubich, W.P., Bergeron, R.J., Samejima, K., and Marton, L.J. 1989. *Cancer Res.* 49: 5591-5597; Pegg, A.E., Wechter, R., Pakala, R., and Bergeron, R.J. 1989. *J. Biol. Chem.* 264: 11744-11749; Pegg, A.E., Nagarajan, S., Naficy, S. and Ganem, B. 1991. *Biochem. J.* 274: 176-171; Porter, C.W., Ganis, B., Libby, P.R. and Bergeron, R.J. 1991. *Cancer Res.* 51: 3715-3720).

More recently, a high-molecular weight ($M_r=25\text{kD}$) spermine polymer has been described by Aziz *et al.* in USP 5,456,908, as a competitive inhibitor of polyamine transport, with a K_i in the 10^{-6}M range. In this patent document are disclosed two novel classes of polyamine transport inhibitors of high molecular weight, namely polymeric conjugates of normally transported substances (TS) of the structure $(\text{TS})_m$ or conjugates of a polyamine and a protein or polypeptide (P) linked by known coupling agents and represented by $(\text{TS})-(\text{P})$, wherein the repeating units of the polymer comprise the targeted polyamine. It is predictable that the inhibitors of Aziz *et al.* would be difficult to eliminate *in vivo* due to their high molecular weight and the high positive charge of the polymers,

THIS PAGE BLANK (USPTO)

notwithstanding the risk of immunogenicity inherent to such high molecular weight inhibitors. The length of the polymers of Aziz *et al.* as well as their charge would cause their adsorption to the cellular surface, which bears negative charges due to the presence of glycoproteins, e.g. sialic acid. Poly-L-lysine, a commercially used compound analogous to high molecular weight polymers of polyamines by its positive charges, is known to promote a strong electrostatic interaction between the cell and its substrate, as in the induction of positive charges of gamma irradiation of synthetic polymers used to produce dishes for tissue culture. The polyamine transport inhibitors of Aziz *et al.* present the additional drawback of being highly cytotoxic. It is noteworthy that their spermine polymer is effective in decreasing contents of polyamines in cells even when not used in combination with DFMO and at concentrations much higher than those required to block polyamine uptake, which indicates inherent high toxicity of the compound toward the cell by a mechanism independent of polyamine transport *per se*. The cytotoxicity of the spermidine polymer of Aziz *et al.* is most probably explained by a non-specific effect on cellular physiology such as the cellular membrane. Although the authors pretend to demonstrate the specific action of the polymers with the fact that exogenous spermidine reverses the induced cytotoxicity, it is highly likely that competition between spermidine and the polymers modifies the electrostatic interaction with the negatively-charged sites on the cellular membrane is responsible for the effect. The results obtained by Aziz *et al.* indicate that at least part of the effect observed with high molecular weight polymers is non-specific (Aziz, S.M., Tofiq, S.F., Gosland, M.P., Olson, J.W. and Gillespie, M.N. 1995. *J. Pharmacol. Exp. Ther.* 274, 181-196). The usefulness of this spermine polymer for specifically blocking polyamine accumulation is therefore uncertain in view of its marked cytotoxicity.

Cysteamine and aliphatic monoamines of similar chain length such as n-butylamine and n-pentylamine have a low but significant ability to antagonize putrescine uptake (Gordonsmith, R.H., Brooke-Taylor, S., Smith, L.L. and Cohen, G.M. 1983. *Biochem. Pharmacol.* 32, 431-437), although the mode of inhibition of these compounds has not been reported. The only polyamine-like structure known to interact non-competitively with the polyamine transport system is pentamidine, an aromatic diamidine (Jones, H.E.,

THIS PAGE BLANK (USPTO)

Blundell, G.K., Wyatt, I., John, R.A., Farr, S.J. and Richards, R.J. 1992. *Biochem. Pharmacol.* 43, 431-437), but the structural basis of its inhibitory activity is not yet clear.

It follows that there still exists a need for effective polyamine transport inhibitors which, while inhibiting the transport of polyamines, will not be internalized by the transport system and will not be toxic to the cell. The availability of low molecular weight inhibitors of polyamine transport would provide for the possibility of better renal elimination, as well as lower risks of being immunogenic. The availability of high-affinity, specific, but impermeant antagonists of polyamine transport would also allow to evaluate the antitumor efficacy of polyamine depletion strategies in vivo with minimal systemic cytotoxic effects.

There is much preclinical evidence supporting the hypothesis that the efficacy of the suicide inhibitor of ornithine decarboxylase, D,L- α -difluoromethylornithine (DFMO = Eflornithine) as a chemotherapeutic agent is limited by the enhanced ability of tumor cells to transport polyamines from plasma sources. Plasma polyamines are partly derived from various plasma sources (7, 12, 18, 58-60, 62, 70) and from the activity of the gastrointestinal microflora, which produces and excretes very high amounts of putrescine and cadaverine (1, 17, 45, 50, 62, 70), which can enter the general circulation through the enterohepatic pathway (6, 45). Other systemic contributions can also be attributed to polyamine excretion by peripheral tissues, including dying tumor cells (32, 35, 41, 42, 63, 64, 67, 79, 80). The enhanced uptake of polyamines by tumor cells results both from the increased polyamine transport activity that accompanies the malignant phenotype (11, 43, 51, 68, 69), and from the effect of DFMO itself, which causes a compensatory upregulation of polyamine uptake across the plasma membrane (9, 10, 14-16, 22, 25, 29, 31, 38, 39, 43, 47, 48, 50, 57, 61). One possible strategy that could be used to overcome this phenomenon would be to administer a pure antagonist of polyamine transport, i.e. a drug which binds with high affinity to the polyamine transporter, but which cannot be transported by this membrane protein. While a need continues to exist for such compound, no such compound is yet available.

SUMMARY OF THE INVENTION

THIS PAGE BLANK (USPTO)

In accordance with the present invention, there is now provided polyamine transport inhibitors having a low molecular weight, less susceptible to immunogenicity and to non-specific interactions with the cellular membrane. These inhibitors have high affinity, are specific, impermeant, pure antagonists of polyamine transport in mammalian cells while exhibiting minimal cytotoxic effects.

There is thus provided in accordance with the present invention synthetic derivatives of original polyamines. In some aspects, the original polyamine is modified to comprise an amido group immediately linked to a carbon atom of said original polyamine, said synthetic derivatives inhibiting the cellular uptake of natural polyamines by specifically binding cellular transporters for said natural polyamines. Surprisingly, the immediate vicinity of the amido group to the backbone of the original polyamine preserves the specificity of the derivative towards the transporter while conferring thereto an impermeant character, providing a true antagonist. In some embodiments, the amido group is located between two internal nitrogen atoms of the original polyamine. In other embodiments, the synthetic derivative comprises a dimer wherein monomers of said dimer are linked together by a spacer side chain anchored to the amido group of each monomer.

Although natural polyamines, such as putrescine, spermine and spermidine, can be used as the original polyamine, other non-natural polyamines can be used as a starting material for the making of synthetic derivatives of the present invention.

Accordingly, a synthetic derivative comprising the following general formula:

provides the structure of some embodiments of the invention, wherein R_1 and R_1' independently represent a hydrogen atom or an alkyl group having 1 to 2 carbon atoms, R_2 , R_2' , or R_3 and R_3' independently represent a hydrogen atom or a methyl group, w and z

THIS PAGE BLANK (USPTO)

independently represent an integer of 3 or 4, x represents an integer from 0 to n, y represents an integer from 0 to n, n represents an integer from 3 to 6, the sum of x and y equals n, and L represents a hydrogen atom or a molecule which cannot be captured by said natural polyamine transporter. The side chain or linker L may be labeled and be used as a marker for a polyamine transporter. Furthermore, the side chain L can be varied to increase the affinity of the derivative for the transporter. The side chain L may also become a spacer molecule useful in the formation of a dimer. This spacer side chain comprises a linear hydrocarbon-containing backbone of 3 to 8 atoms. The backbone may comprise sulfur, oxygen, or nitrogen atoms.

In yet other embodiments, the original polyamine is spermine. Three derivatives have been obtained therefrom: *N*-(2-mercaptoethyl)spermine-5-carboxamide (MESC), the disulfide from thereof, namely 2,2'-dithiobis(*N*-ethyl-spermine-5-carboxamide) (DESC), and *N*-[2,2'-dithio(ethyl,1-aminoethyl)]spermine-5-carboxamide (DEASC).

It is an object of the invention to provide the use the above synthetic derivatives for inhibiting the activity of a natural polyamine transporter. In some embodiments, the method may be described as comprising the step of contacting said transporter with an inhibitory effective amount of said synthetic derivative. This inhibition results in the control of the treatment of disorders involving unrestrained cell proliferation and/or differentiation where control of polyamine transport is required, when used in combination with an inhibitor of polyamine synthesis such as DFMO.

It is further another object of the invention to provide a use of the non-dimeric derivatives as a marker for a polyamine transporter, which comprises the steps of labeling said synthetic derivative, binding to said transporter said labeled synthetic derivative and detecting said bound labeled marker as an indication of the presence of said polyamine transporter. The above sequence of steps results in the diagnosis of a disorder involving unrestrained cell proliferation and/or differentiation where control of polyamine transport is required.

It is also another object of the invention to provide a pharmaceutical composition for treating disorders wherein control of polyamine transport is required, comprising anyone of the above derivatives in adjunction with an acceptable pharmaceutical carrier.

THIS PAGE BLANK (USPTO)

Preferably, this composition also comprises an inhibitor of polyamine synthesis, such as DFMO.

The applicants have unexpectedly discovered that the presence of a lateral amido group immediately linked to a carbon atom of the polyamine backbone of a synthetic derivative of an original polyamine confers impermeant properties to the so derived synthetic polyamine against the mammalian cell. It follows that the synthetic polyamine derivatives of the present invention, by exhibiting high affinity for diamine and polyamine transport systems, block the transport of natural polyamines by competing therewith, while in the same time acting as poor substrate for intracellular uptake. The affinity of the polyamine derivative for the transporter system is further enhanced by increasing the length of a side chain anchored to the amido group of the derivative. The best affinity is achieved by dimerizing the polyamine derivative with the aid of a spacer molecule anchored at both ends to the amido group of each monomer. The flexibility of the chemical structure of the inhibitors of the present invention permits better optimization of the activity and affinity than a simple polymeric structure such as $(TS)_n$. For example, modifications to the polyamine backbone as taught by the present invention, such as methylation of C1 and C12, lowers the possibility of oxidation of the primary amides by the serum amine oxidase, which is present in mammalian sera. Additional modifications including adjunction to the lateral chain of alkylating groups that irreversibly modify residues that are essential to the activity of the polyamine transporter, such as carboxylic moieties of the carrier protein, are also contemplated in the present invention (Torossian, K., Audette, M., and Poulin R., 1996. *Biochem. J.* **319**: 21-28). The inhibitory action of the derivatives of the present invention is thus enhanced. By diminishing the amount of active transporters, additional modifications to the side chain that can be of potential therapeutic interest include the incorporation of reactive groups to the side chain that would allow the covalent modification of residues in the polyamine transporter by the principle of affinity labeling, and its subsequent irreversible inactivation.

This finding clearly demonstrates that modification of the chemical structure of the lateral chain optimizes the affinity of the polyamine derivative without augmenting to a great extent the molecular weight thereof. This markedly contrasts with the teachings of Aziz *et al.* who make use of high molecular weight polymers. Moreover, the mode of

THIS PAGE BLANK (USPTO)

action of the inhibitors herein proposed, clearly different to that of Aziz *et al.* which relies upon their inherent cytotoxicity, is a competitive inhibition of the polyamine uptake.

Specific transport inhibition by polyamines dimerized via a side group on an integral atom of the polyamine chain is not limited to spermine or spermine-like dimers, but can also be obtained with dimers of triamines such as spermidine [*N* - (3-aminopropyl)-1,4-diaminobutane], *sum*-homospermidine [*n* - (4-aminobutyl)-1,4-diaminobutane] and *sym*-norspermidine [*N* - (3-aminopropyl)-1,3-diaminopropane]. We have synthesized novel spermidine, *sym*-homospermidine and *sym*-norspermidine dimers cross-linked through aliphatic or aromatic side chains on the central secondary amino group. We have found that such compounds act as inhibitors of polyamine transport with a potency similar or greater than that of dimeric polyamine transport inhibitors with a spermine-like backbone such as 2,2'-dithiobis[*N*-ethyl-spermine 5-carboxamide (or DESC)].

In some embodiments, one spermidine or *sym*-norspermidine chain is cross-linked to a second spermidine or *sym*-norspermidine chain with an N-alkyl spacer side group anchored to the secondary amino group of said spermidine or *sym*-norspermidine chain. In particular embodiments, said spacer side group is an aliphatic carbon chain or an aromatic carbon chain.

Other objects, advantages and features of the present invention will become more apparent upon reading of the following non restrictive description of preferred embodiments thereof, given by way of example only and with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

In the appended drawings:

FIG 1 illustrates details of the synthesis of the compounds of the present invention, wherein a=triethylamine; b=di-*tert*-butyl dicarbonate; c=cyanuric chloride; d=cystamine dihydrochloride; e=3 N HCl; f=dithiothreitol; g=50 mM sodium phosphate in aqueous solution (pH=8.0); and wherein compound I is 5-carboxyspermine; compound II is tetra-Boc-5-carboxyspermine; compound III is 2,2'-dithiobis[*N*-ethyl-(*N*¹, *N*⁴, *N*⁸, *N*¹²)-tetra-Boc-spermine-5-carboxamide; compound IV is *N*-[2,2'-dithio(ethyl, 1'-aminoethyl)]-*N*¹, *N*⁴, *N*⁸,

THIS PAGE BLANK (USPTO)

N^{12} -tetra-Boc-spermine-5-carboxamide; compound V is 2,2'-dithiobis(*N*-ethyl-spermine-5-carboxamide) octahydrochloride (DESC); compound VI is *N*-[2,2'-dithio(ethyl,1'-aminoethyl)]-spermine-5-carboxamide pentahydrochloride (DEASC) and compound VII is *N*-(2-mercaptoethyl) spermine 5-carboxamide (MESC) tetrahydrochloride;

5 FIG 2 graphically illustrates the inhibition of [14 C]spermine transport by MESC, DESC and DEASC in human ZR-75-1 breast cancer cells. The rate of spermine uptake was measured in ZR-75-1 cells grown as monolayers in 24-well culture plates in the presence of the indicated concentrations of DESC (○), MESC (●), and DEASC (□), using 1 μ M [14 C]spermine as substrate. Data are the mean \pm SD of triplicate determinations;

10 FIG 3 graphically illustrates the inhibition of [3 H]spermidine uptake by spermine and DESC in ZR-75-1 cells. The rate of spermidine uptake was measured in ZR-75-1 cells grown as monolayers in 24-well culture plates in the presence of the indicated concentrations of spermine (○) and DESC (●) using 3 μ M [3 H]putrescine (A) or 1 μ M [3 H]spermidine (B) as substrate. Data are the mean \pm SD of triplicate determinations from
15 a representative experiment;

 FIG 4 illustrates graphically the Lineweaver-Burke analysis of putrescine transport inhibition by DESC and DEASC in ZR-75-1 cells. The rate of [3 H]putrescine uptake was determined in ZR-75-1 cell cultures with increasing concentrations of substrate (A) in the presence of 0 μ M DESC (○), 3 μ M DESC (●), 30 μ M DESC (□) or 100 μ M DESC (■)
20 or (B) in the presence of 0 μ M DEASC (○), 20 μ M DEASC (●), 50 μ M DEASC (□) or 200 μ M DEASC (■);

 FIG 5 illustrates graphically the structure of MESC thioether derivatives and their K_i values with respect to spermidine uptake in CHO-K1 cells. The various conjugates were prepared from MESC as described supra, and structure and name of the substituents are
25 given in the first two columns from the left, wherein R corresponds to the group attached to sulfur in MESC (structure VII, Fig. 1). The rate of spermidine uptake was determined in CHO-K1 cells in the presence of increasing concentrations of the various MESC derivatives, using 1 μ M [3 H]spermidine as substrate. K_i values are given as the mean \pm SD of triplicate determinations from 2 to 3 experiments;

30 FIG 6 graphically represents the effect of DESC and MESC on the intracellular accumulation of [3 H]spermidine in ZR-75-1 cells, wherein at time 0 (A), 5 μ M

THIS PAGE BLANK (USPTO)

[³H]spermidine was added to ZR-75-1 cell cultures grown in 24-well plates (1ml/well) in the presence of 200 μ M MESC (●), 50 μ M DESC (□) or 200 μ M DESC (■), and accumulation of radio-labeled spermidine determined after the indicated interval. Control cells (○) received vehicle only. B, same as in A, except that 200 μ M CHX was added at time 0 in the presence of 0 (●), 50 (□) or 200 μ M DESC (■). Data are the mean \pm SD of triplicate determinations;

FIG 7 illustrates the effect of spermine, MESC, DESC and DEASC on ZR-75-1 cell proliferation. Cells were incubated for 11 days in MEZR medium with the indicated concentration of spermine, DESC, MESC, or DEASC in the presence (shaded bars) or absence (plain bars) of 1 mM of aminoguanidine, and DNA content per culture was then determined. Data represent the mean \pm SD of triplicate determinations;

FIG 8 represents the effect of DESC on the reversal of DFMO-induced growth inhibition by exogenous spermidine in ZR-75-1 cells. Cells were incubated for 11 days in SD medium with the indicated concentrations of spermidine in the presence of 50 μ M DESC (●), 1mM DFMO (□), or the combination thereof (■), or in the absence of drugs (○). Data are the mean \pm SD of triplicate cultures;

FIG 9 represents the chromatographic profile of DESC and its degradation products in IMEM or PBS. DESC (50 μ M) was added to 1ml of IMEM containing 10% fetal bovine serum in the absence (A) or presence (B) of 1mM aminoguanidine, or 1 ml PBS (C) in 24-well culture plates in the absence of cells. Media were analyzed after 20 minutes (solid lines) or 48 hours (dotted lines) of incubation at 37°C in 95% air: 5% CO₂, water-saturated atmosphere for amine composition by ion-pair reversed-phase HPLC as described supra. Peaks 1 and 2 are degradation products of DESC, whereas peak 3 is a minor amount of DEASC initially present in the DESC preparation. Note the disappearance of peak 3 (DEASC) and the appearance of a shoulder (indicated by the arrow) at 42 minutes on the 48-hour profile in panel A; and

FIG 10 represents the time course of degradation of DESC in growth medium. At time 0, 50 μ M DESC was added to 1ml of IMEM in 24-well culture plates and the content in DESC (○), compound 1 (Comp 1, ●) and compound 2 (Comp 2, □) determined by HPLC after the indicated incubation period at 37°C in a 5% CO₂ atmosphere. Data represent the mean of triplicate determinations from a representative experiment.

THIS PAGE BLANK (USPTO)

FIG 11. Structures of putrescine, of the natural polyamines spermidine and spermine, and of three cell-impermeant inhibitors of polyamine transport (DESC, DEASC and MESC).

FIG 12. Structure and scheme for the synthesis of unmethylated spermine analogs as polyamine transport inhibitors with a linker attached via amide bonds to the polyamine chains (BS-3, BS-4, BS-5 and BS-6 compounds). The method of synthesis is described in greater detail in Example 1.

FIG 13. Initial route of synthesis of terminal C-methylated, dimeric spermine analogs as transport inhibitors with a linker attached via an alkyl bond to the polyamine chains (BMS-3, BMS-4, BMS-5 and BMS-6). The steps presented in this figure describe the complete route of synthesis leading to the precursor N' , N' , N^8 , N'^2 -tetra (Boc)-1, 12-dimethylspermine-5-carbinol (XV).

FIG 14. The first step in the coupling of N' , N' , N^8 , N'^2 -tetra (Boc)-1, 12-dimethylspermine-5-carbinol (XV) to the linker L (= a N -mono-FMOC-diaminoalkane), toward the synthesis of BMS compounds.

FIG 15. The second step in the coupling of N' , N' , N^8 , N'^2 -tetra (Boc)-1, 12-dimethylspermine-5-carbinol (XV) to the linker L (= a N -mono-FMOC-diaminoalkane) toward the synthesis of BMS compounds.

FIG 16. The final step of the synthesis of BMS compounds (XX); the Boc-protected, cross-linked 1, 12-dimethylspermine dimer is deprotected to generate the BMS compounds. BMS-3, BMS-4, BMS-5 and BMS-6 correspond to N^w , N^w -bis ([1, 12-dimethyl-spermine]-5-methyl)-diaminoalkanes where the diaminoalkane linker is 1,3-diaminopropane, 1,4-diaminobutane, 1,5-diaminopentane, and 1,6-diaminohexane, respectively.

FIG 17A, 17B and 17C presents three classes of dimeric polyamine transport inhibitors according to the site of attachment of the linker (L) to the polyamine chain.

FIG 17A - C-linked dimeric analogs. R_1 is H, methyl, ethyl or propyl; R_2 is H or methyl; R_3 is an alkyl, amide, keto, ether, thioether, phosphono or sulfonyl group; x is greater than 2 and less than 5 ($2 < x < 5$), and the sum of $y+z$ is greater than or equal to 2 and less than or equal to 6 ($2 \leq y + z \leq 6$). The linker L is any chemical structure covalently linked to the R_3 groups and which prevents the uptake of the analog.

THIS PAGE BLANK (USPTO)

FIG 17B - *N*-linked dimeric analogs. R_1 is H, methyl, ethyl or propyl; R_2 is H or methyl; x is greater than 2 and less than 8 ($2 < x < 8$), and w is greater than 2 and less than 7 ($2 < w < 7$). The linker *L* is any chemical structure covalently linked to one internal amino group of each polyamine chain and which prevents the uptake of the analog.

5 FIG 17C - C-linked/*N*-linked mixed dimeric analogs. R_1 is H, methyl, ethyl or propyl; R_2 is H or methyl; x is greater than 2 and less than 5 ($2 < x < 5$), the sum of $y+z$ is greater than or equal to 2 and less than or equal to 6 ($2 \leq y + z \leq 6$), and w is greater than 2 and less than 8 ($2 < w < 8$). The linker *L* is any chemical structure covalently linked to one internal amino group of one polyamine chain and to the R_3 of the other polyamine chain, and which prevents the uptake of the analog.

10 FIG 18. Initial route of synthesis of unmethylated, N^4 -alkylated dimeric spermine analogs (FIG 17B). Steps leading to the synthesis of the intermediate N^1 -benzyl, N^8 , N^{12} -di(CBZ)-spermine.

15 FIG 19. Final steps for the synthesis of unmethylated, N^4 -alkylated dimeric spermine analogs (FIG 17B, represented by type compound XXIX). For the aliphatic linker $-(CH_2)_n-$, $2 < n < 51$.

20 FIG 20. Initial route of synthesis of terminal C-methylated, N^4 -alkylated dimeric spermine analogs (FIG 17B). Steps leading to the synthesis of the intermediate N^α , N^ω -bis (N -[N^1 -Boc-3-amino, 3-methylpropyl], N -[4-aminobutyl]) $-\alpha\omega$ -diminoalkane. For the aliphatic linker $-(CH_2)_n-$, $2 < n < 51$.

FIG 21. Final steps for the synthesis of terminal C-methylated, N^4 -alkylated dimeric spermine analogs (FIG 17B, represented by type compound XXXVIII). For the aliphatic linker $-(CH_2)_n-$, $2 < n < 51$.

25 FIG 22. Initial route of synthesis of 1,12-dimethylspermine dimers cross-linked through N^4 -alkyl/5-alkyl attachments of the linker (FIG 17C). Steps leading to the synthesis of the intermediate N^α /(N^1 -Boc-3-amino, 3-methylpropyl], N -[N^1 -Fmoc-4-aminobutyl]), N^ω -[5-(N^1 , N^4 , N^8 , N^{12} -tetra (Boc)-spermine)-methyl]- α , ω -diaminoalkane. For the aliphatic linker $-(CH_2)_n-$, $2 < n < 51$.

30 FIG 23. Intermediate route of synthesis of 1,12-dimethylspermine dimers cross-linked through N^4 -alkyl/5-alkyl attachments of the linker (FIG 17C). Steps leading to the synthesis of the intermediate N^α /(N^1 -Boc-3-amino, 3-methylpropyl], N -[8-amino-5-aza-

THIS PAGE BLANK (USPTO)

octanoyl]], N^{ω} -[5-(N^1 , N^4 , N^8 , N^{12} -tetra (Boc)-spermine)-methyl]- α , ω -diaminoalkane. For the aliphatic linker $-(CH_2)_n-$, $2 < n < 51$.

FIG 24. Final route of synthesis of 1,12-dimethylspermine dimers cross linked through N^4 -alkyl/5-alkyl attachments of the linker (FIG 17C represented by type compound XLV). For the aliphatic linker $-(CH_2)_n-$, $2 < n < 51$.

FIG 25 illustrates the structure of representative dimeric transport inhibitors with a triamine backbone that are included in the present invention. BABAC is N,N' -bis(3-aminopropyl), N,N' -bis(4-aminobutyl)cystamine, a dimeric spermidine derivative with a diethyl disulfide linker; (BNSpd-(n+2)) (standing for *bis*(sym-norspermidine) molecules with a carbon chain length of n+2 atoms; $0 < n < 7$) represents the general structure of dimeric *sym*-norspermidine-derived transport inhibitors with an aliphatic linker; BSpd-(n+2) (standing for *bis*(spermidine) molecules with a carbon chain length of n+2 atoms; $0 < n < 7$) represents the general structure of dimeric spermidine-derived transport inhibitors with an aliphatic linker; TADAX is N,N,N',N' -tetrakis(3-aminopropyl)-*p*-xylylenediamine, a dimeric *sym*-norspermidine derivative with a *p*-xylylenediamine linker.

FIG 26 illustrates the structure of other representative dimeric transport inhibitors with a triamine backbone that are included in the present invention. BABA-trans and BABA-cis stands for the *trans* and *cis* isomers of $N,N'-N,N'$ -bis(3-aminopropyl), N,N' -bis(4-aminobutyl) derivatives of α,α' -diaminoalkenes, which are dimeric derivatives of either *sym*-homospermidine, *sym*-norspermidine or spermidine. BABA-yne stands for $N,N'-N,N'$ -bis(3-aminopropyl), N,N' -bis(4-aminobutyl) derivatives of α,α' -diaminoalkynes, which are dimeric derivatives of either *sym*-homospermidine, *sym*-norspermidine or spermidine.

FIG 27 illustrates synthetic Scheme 1 used to obtain dimeric *sym*-norspermidine-derived polyamine transport inhibitors (X) from a precursor cross-linking diamine (VIII) containing the linker (L), and typical examples of said linker. Et_3N =triethylamine.

FIG 28 illustrates synthetic Scheme 2 used to obtain dimeric *sym*-homospermidine, *sym*-norspermidine-, or spermidine-derived polyamine transport inhibitors (XIV) from the parent triamine (XI) cross-linked with a linker L via symmetrical *N*-alkylation of the secondary amino group of said triamine, and typical examples of said linker. $TrCl$ =trityl chloride; Et_2NH =diethylamine; DMF=dimethylformamide.

THIS PAGE BLANK (USPTO)

FIG 29 illustrates synthetic Scheme 3 used to obtain dimeric *sym*-homospermidine-, *sym*-norspermidine-, or spermidine-derived polyamine transport inhibitors (XIV) from the trityl-protected parent triamine (XII) cross-linked with a linker L via symmetrical amidation of the secondary amino group of said triamine followed by reduction of the amide bonds, and typical examples of said linker. THF=tetrahydrofuran.

FIG 30 illustrates synthetic Scheme 4 used to obtain dimeric *sym*-homospermidine-, *sym*-norspermidine-, or spermidine-derived polyamine transport inhibitors (XVIII) from the parent triamine (XI) cross-linked via a diethyl disulfide linker L by symmetrical alkylation of the secondary amino group of said triamine. TFA=trifluoroacetyl.

FIG 31 illustrates a comparison between the structures of *N,N'*-bis(3-aminopropyl),*N,N'*-bis(4-aminobutyl)cystamine (BABAC), a dimeric spermidine derivative with a diethyldisulfide linker, of its monomeric thiol form *N*-(3-aminopropyl),*N*-(4-aminobutyl)cysteamine (AAC) and of 2,2'-dithiobis[*N*-ethyl-spermine 5-carboxamide (DESC).

FIG 32 [A-32C] represents the inhibition of [³H]putrescine (32A), [³H]spermidine (32B) and [¹⁴C]spermine uptake (32C) by spermine (SPM), DESC, BABAC and AAC in human breast cancer cells ZR-75-1. Data represent the mean of triplicate determinations from a representative experiment. Standard deviations, which did not exceed 10% of the mean value, were not shown for the sake of clarity.

FIG 33 represents the inhibition of [¹⁴C]spermine uptake by spermine (SPM), DESC and TADAX in ZR-75-1 human breast cancer cells. Data are the mean ±SD of triplicate determinations from a representative experiment.

FIG 34 represents the relative cytotoxicity of *sym*-norspermidine (NSpd), BABAC and TADAX in ZR-75-1 human breast cancer cells. Data are the mean ± SD of triplicate determinations from a representative experiment.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Materials and Methods:

Sym-norspermidine, ornithine dihydrochloride and other reagents for organic
5 syntheses were purchased from Aldrich (Milwaukee, WI) and Sigma (St. Louis, MO).
Reversed phase silica gel liquid chromatography was performed with a Lichroprep™ RP-
18 C₁₈ silica gel column (40-63 μM ; BDH, St. Laurent, Qc., Canada) using a gradient of
CH₃CN:MeOH:H₂O (25:35:40 to 50:30:20) as eluent. Homogeneity of synthetic products
was assessed by thin-layer chromatography performed on 0.20 mm F₂₅₄ silica gel 60 plates
10 or 0.25 mm F₂₅₄S RP-18 reversed phase silica gel plates (E. Merck, Darmstadt, Germany).
FIR spectra were obtained on a Perkin-Elmer 1600 spectrophotometer (FTIR series) and
were expressed in cm⁻¹. ¹H and ¹³C NMR spectra were recorded with a Bruker AC/F 300
(300 MHz); ¹³C were recorded at 75.47 MHz. Chemical shifts (δ in ppm) were referenced
to CDCl₃ (7.26 ppm for ¹H and 77.00 ppm for ¹³C). Mass spectra (MS) were recorded at
15 the Mass Spectrometry Regional Center (University of Montreal, Montreal, Qc., Canada)
by fast atomic bombardment mass spectrometry (FABMS) or liquid secondary ion mass
spectrometry (LSMIS), using a VG AutoSpecQ™ and a Kratos MS50 TCTA, respectively.

[2,3-³H(N)]putrescine dihydrochloride (4.1 x 10⁴ Ci/mol) and [1,8-³H(N)]spermidine
trihydrochloride (1.5 x 10⁴ Ci/mol) were obtained from Dupont-New England Nuclear
20 (Lachine, Qc., Canada). [5,8-¹⁴C]spermine tetrahydrochloride (108 Ci/mol) was purchased
from Amersham (Arlington Heights, IL). DFMO was provided by the Marion Merrell Dow
Research Institute (Cincinnati, OH). Fetal bovine serum (FBS) and Cosmic™ calf serum
were from Hyclone (Logan, UT). The heterobifunctional reagent 1(-p-azidosalicylamido)-
4-iodoacetamido)butane (ASIB) as obtained from Pierce (Rockford, IL). Lucifer Yellow
25 (OY) iodoacetamide was purchased from Molecular Probes (Eugene, OR). Putrescine
dihydrochloride, spermidine trihydrochloride, spermine tetrahydrochloride, iodoacetamide,
5,5'-dithio(2-nitrobenzoic acid) and 3,4-diaminobenzoic acid as well as tissue culture
reagents were purchased from Sigma. *Ortho*-phthaldialdehyde was purchased from Fluka
(Ronkonkoma, NY) and other reagents for high-performance liquid chromatography
30 (HPLC) were from Fisher Scientific (Montreal, Qc., Canada) or Aldrich (Milwaukee, WI).

THIS PAGE BLANK (USPTO)

Synthesis of 5-carboxyspermine (compound I)

Unless otherwise indicated, reactions were performed at room temperature. Compound I of Figure 1, namely 5-carboxyspermine, was synthesized using a known scheme (Behr, J.P. 1989. *J. Chem. Soc., Chem. Commun.* 101-103). Briefly to a stirred solution of 10.0 g (59.3 mmol) of ornithine hydrochloride dissolved in 250 ml MeOH were added 18.0 g (197 mmol) of tetramethylammonium hydroxide. After dissolution of ornithine salt, MeOH was evaporated, the mixture was then dissolved in 350 mL of dry dimethylformamide (HPLC grade; Aldrich, Milwaukee, WI) and the residual ammonium salt was filtrated, yielding ornithine as its free base. Following the addition of acrylonitrile (2.2. equivalents, 130.9 mmol), the mixture was stirred for 16 hours in the dark to give 10.6 g (yield=74%) of crude *N^α,N^β*-diethylcyanide ornithine, which was subsequently used without further purification. White solid: IR (film) ν cm^{-1} 3372 (OH, acid), 2247 (CN); ^1H NMR δ (CDCl_3 , 300 MHz) 1.48 (m, 4H, CH_2CHCOOH), 2.63 (m, 6H, 3 X CH_2N), 2.86 (2xt, $J_1 = 5.9$ and $J_2 = -2.7$ Hz, 4H, 2 X CH_2CN), 3.07 (t, $J = 7.2$ Hz, 1H, CHCOOH). To obtain 5-carboxyspermine KOH (2.7g, 48.0 mmol) was dissolved with vigorous stirring in 8 ml of 95% (v/v) EtOH and 10.5 g (44.1 mmol) of *N^α,N^β*-diethylcyanide ornithine were then added. The resulting mixture was placed under H_2 at 40 psi in a Burgess-Parr hydrogenator, using 2.09 g (24.4 mmol) or Raney nickel as catalyst (Behr, J.P. 1989. *J. Chem. Soc., Chem. Commun.* 101-103; Bergeron, R.J. and Garlich, J.R. 1984. *Synthesis*: 782-784). After 22 hours, Raney nickel was removed by filtration, and the solvent evaporated *in vacuo*, yielding 16.07 g of crude 5-carboxyspermine potassium salt. Yellow oil; IR (film) ν cm^{-1} 3363 (OH, acid), 2937 (NH_2) no cyanide band; ^1H NMR δ (CDCl_3 , 300 MHz) 1.53 (m, 2H, CH_2NH_2), 2.65 (m, βH , CH_2NH), 3.09 (t, $J = 5.7$ Hz, 1H, CHCOOH).

Synthesis of 2,2'-Dithiobis(*N*-Ethyl-Spermine-5-Carboxamide) (DESC) and *N*-[2,2]-Dithio(Ethyl, 1'-Aminoethyl)] spermine-5-Carboxamide (DEASC)

Amine protection of 5-carboxyspermine by *tert*-butyl carbonyl (Boc) groups was performed as described (Ponnusamy, E., Fotadar, U., Spisni, A. and Fiat, D. 1986. *Syntheses*: 48-49). To 16.0 g (65.0 mmol) of crude 5-carboxyspermine potassium salt dissolved in 1.5 L MeOH were added 9.64 ml of 10% (v/v) triethylamine and 54.3 g (4.4

THIS PAGE BLANK (USPTO)

equivalents, 286 mmol) of di-*tert*-butyl dicarbonate. After stirring for 24 hours, solvent was evaporated, 100-150 ml H₂O were added and the resulting mixture was chilled at 0°C. After adjusting pH at 2.2 with 2 N HCl, the Boc-product was extracted with ethyl acetate, dried over anhydrous MgSO₄ and purified by C₁₈ reversed phase silica gel chromatography, yielding 3.3 g of pure tetra-Boc-5-carboxyspermine (Compound II, Fig. 1). Light yellow solid; IR (film) ν cm⁻¹ 3356 (OH, acid), 1682 (C=O, amide); ¹H NMR δ (CDCl₃, 300 MHz) 1.32 (2 x s, 36 H, (CH₃)₃C from Boc-N), 1.90-1.40 (m, 9H, CH₂CH₂N), 3.20-2.90 (m, 10H, CH₂N); M (for C₃₁H₅₈O₁₀N₄) - 646.41; m/z (LSIMS) = 647.42 [(M+1)*]. Coupling of tetra-Boc-5-carboxyspermine (compound II) to cystamine was then performed in two steps based on the method of Venkataraman (Venkataraman, K. 1979. *Tetrahedr. Lett.* 32, 3037). To a solution of 1.15 g (1.78 mmol) of compound II in 20 ml dry acetone was added 0.27 mL (1.1 eq, 1.96 mmol) of triethylamine (freshly distilled on KOH) and 361 mg (1.1 eq, 1.96 mmol) of cyanuric chloride and the reaction mixture stirred overnight under N₂ to form the corresponding acid chloride. Cystamine dihydrochloride (241 mg; 1.07 mmol) was then suspended in dry triethylamine and added to the acid chloride form of compound II, with the resulting triethylamine concentration being at ≥ 4 -fold excess relative to the latter. After stirring for 12 hours, the residual triazine oxide was filtrated, acetone was evaporated and the product extracted with CHCl₃, dried over anhydrous MgSO₄ and evaporated *in vacuo*. The crude compound was then purified by reversed-phase C₁₈ column chromatography, yielding 0.682 g of 2,2'-dithiobis[*N*-ethyl-(*N'*,*N*4,*N*^x,*N'*¹²-tetra-Boc-5-carboxamide (compound IV, Fig. 1). (m) Yellow oil; IR (film) ν cm⁻¹ 1693 (C=O, amide); ¹H NMR δ (CDCl₃, 300 MHz) 1.38 (s, 36H, (CH₃)₃C), 1.59 (m, 8H, CH₂CH₂CH₂), 2.53 (6, *J*=5.7 Hz, 1H, CONHCH₂), 2.73 (t, *J*=6.1Hz, 2H, CH₂S), 3.11 (m, 10H, CH₂NH), 3.51 (m, 2H, NCH₂CH₂S):M (for C_{xx}H₁₂₄O₁₈N₁₀S₂) = 1408.85; m/z (FABMS) = 1409.9 [(M+1)*].

Compound III (215 mg in MeOH) was then deprotected by addition of 1 ml of 3 N HCl, bringing the pH from 6.0 to \approx 0.5. After stirring vigorously for 15 hours, the solvent was dried out *in vacuo* and the resulting compound purified by cation exchange chromatography with a Dowex 50W-X4 column (dry mesh; 100-200; Sigma) pre-equilibrated with H₂O and successively washed with H₂O, 1 N HCl, 2 N HCl, 4 N HCl and 6N HCl. Ninhydrin-positive fractions eluted with 6 N HCl were pooled and evaporated *in vacuo*, yielding 96 mg of pure 2,2'-dithiobis(*N*-ethyl-spermine-5-carboxamide)-

THIS PAGE BLANK (USPTO)

octahydrochloride (DESC, Compound V, Fig. 1. White solid; mp 75-78°C; bp 118°C, ¹H NMR δ (CDCl₃, 300 MHz) 1.62 (m, 2H, CH₂CHCONH), 1.97-1.80 (m, 6H, CH₂CH₂CH₂), 2.74 (t, *J*=6.2 Hz, 2H, CH₂S), 2.92 (m, 10H, CH₂HN₂), 3.46 (dt, *J*=7.1 Hz, 2H, CH₂CH₂S), 3.84 (t, *J*=7.0 Hz, 1H, CHCONH); M (for C₁₅H₃₀N₅S₂) = 608.96; *m/z* (FABMS) = 609.4 (M⁺).

Compound IV was similarly deprotected to yield *N*-[2,2'-dithio(ethyl, 1'-aminoethyl)]spermine-5-carboxamide (DEASC, Compound VI, Fig. 1). Yellow solid; mp 50-54°C; bp 109°C. ¹H NMR δ (CDCl₃, 300 MHz) 1.89 (m, 2H, CH₂CHCONH), 2.10-2.29 (m, 6H, CH₂CH₂CH₂), 3.04 (t, *J*=6.0 Hz, 2H, CONHCH₂CH₂S), 3.19 (t, *J*=7.4 Hz, 2H, SSCH₂CH₂HN₂), 3.25 (m, 10H, CH₂, NH), 3.51 (t, *J*=6.5 Hz, 2H, SSCH₂CH₂HN₂), 3.78 (m, 2H, CONHCH₂CH₂S), 4.11 (t, *J*=6.7 Hz, 1H, CHCONH). M (for C₁₅H₄₁ON₅S₂) = 380.62; *m/z* (LSIMS) = 381.24.

Synthesis of *N*-(2-Mercaptoethyl)spermine-5-Carboxamide [MESC]

DESC was dissolved in 50 mM sodium phosphate buffer, pH 8.0, containing 250 mM dithiothreitol (DTT), and incubated for 30 minutes at 37°C in a water bath. The mixture was then loaded on a Dowex™ 50W-X4 cation exchange column equilibrated with H₂O, and after washing with 5 column volumes each of 1 N HCl and 2 N HCl, the free thiol was eluted with 10 volumes of 4 N HCl. Amine-containing fractions, as identified by mixing 5 μl aliquots with 200 μl of an *o*-phthaldialdehyde solution (3.7 mM *o*-phthaldialdehyde; 0.4 M boric acid, pH 10.4; 1% v/v MeOH; 0.45% v/v 2-mercaptoethanol; 0.03% w/v Brij 35) and heating for 20 minutes at 37°C, were then pooled. The amount of *N*-(2-mercaptoethyl)-spermine-5-carboxamide [MESC] tetrahydrochloride (compound VII, Fig. 1) thus isolated was titrated for thiol equivalents with 5,5'-dithio-*bis*-(2-nitrobenzoic acid) (Jocelyn, P.C. 1987. *Meth. Enzymol.* 143, 44-67) using either cysteamine or DTT as standard. The yield of MESC using this procedure was virtually 100%, based on the number of thiol equivalents determined with 5,5'-dithio-*bis*-(2-nitrobenzoic acid) and the expected number of thiol equivalents expected per mass of DESC. Finally, MESC purity was confirmed by ion-pair reversed-phase HPLC using post-column derivatization with *o*-phthaldialdehyde (Pegg, A.E., Wechter, R., Poulin, R., Woster, P.M. and Coward, J.K. 1989. *Biochemistry* 28: 8446-8453). ¹H NMR δ (CDCl₃, 300

THIS PAGE BLANK (USPTO)

MHz) 1.91 (m, 2H, CH_2CHCONH), 2.08-2.24 (m, 6H, $\text{CH}_2\text{CH}_2\text{CH}_2$), 2.82 (t, $J=6.3$, 2H, $\text{CONHCH}_2\text{CH}_2\text{SH}$), 3.22 (m, 10H, CH_2NH , 3.56 (m, 2H, $\text{CONHCH}_2\text{CH}_2\text{SH}$), 4.11 (t, $J=6.6$, 1H, CHCONH).

5 **Synthesis of Thioether Adducts of MESC with Iodoacetamides**

To 1 ml of an extemporaneously prepared, DTT-free solution of MESC (20 mM in H_2O) were added 50 μl of 50 mM Tris-HCl (pH 7.0) and 105 μl of a 40 mM solution of either iodoacetamide, LY iodoacetamide or ASIB in a light-protected microcentrifuge tube, and the mixture was incubated for 2 hours at 37°C. The extent of thiol modification was
10 assessed by measuring the amount of thiol remaining at the end of the incubation with 5,5'-dithio-bis-(2-nitrobenzoic acid) as described above, and was determined to be essentially complete. Excess iodoacetamide was then inactivated by adding DTT to a final concentration of 40 mM and incubating the solution for 2 hours at 37°C. The resulting solutions of MESC adduct was used without further purification for [^3H]spermidine uptake
15 assays conducted as described below. The effect of the respective DTT-inactivated iodoacetamide on spermidine transport was determined in parallel by incubating cells with the same reaction mixture from which MESC was omitted.

Cell Culture

20 Both ZR-75-1 human breast cancer cells and Chinese hamster ovary cells (CHO-K1) were obtained from the American Type Culture Collection (Rockville, MD). ZR-75-1 cells were maintained in phenol red-free RPMI 1640 medium supplemented with 10% fetal bovine serum, 2mM L-glutamine, 1 mM sodium pyruvate, 15 mM Hepes, 10 nM 17β -estradiol, and antibiotics [MEZR medium] (Huber, M. and Poulin, R. 1995. *Cancer Res.*,
25 55, 934-943). CHO-K1 cells were routinely grown in α -Minimal Essential Medium supplemented with 10% CosmicTM calf serum in a 5% CO_2 humid atmosphere at 37°C.

Even though the present invention has been described with a certain degree of particularity, it is evident that many alternatives, modifications, and variations will be apparent to those skilled in the art in light of the following disclosure. Accordingly, it is
30 intended that all such alternatives, modifications, and variations which fall within the spirit and the scope of the invention be embraced by the defined claims.

THIS PAGE BLANK (USPTO)

EXAMPLE 1
EFFECT OF INHIBITORS ON CELL PROLIFERATION

For growth studies, ZR-75-1 cells were cultured in MEZR medium or in phenol red-free RPMI 1640 supplemented with 2mM L-glutamine, 1 mM sodium pyruvate, 15 mM Hepes, antibiotics, 1 nM 17 β -estradiol, 0.5 μ g of bovine insulin per ml and 5% (v/v) charcoal-treated fetal bovine serum (SD medium), as indicated in the text. When polyamines or polyamine analogs were added to serum-containing media, 1 mM aminoguanidine was added to inhibit bovine serum amine oxidase (BSAO) activity (Morgan, D.M.L. 1989. in *The Physiology of Polyamines* (Bachrach, U., and Heimer, Y.M. eds) Vol. I, pp. 203-229, CRC Press, Boca Raton). The effect of the transport inhibitors on cell growth was measured by incubating ZR-75-1 cells for 11 days in medium supplemented with antagonist, polyamines and/or 1 mM DFMO as indicated, followed by colorimetric determination of DNA content with 3,4-diaminobenzoic acid (Simard, J., Dauvois, S., Haagensen, D.E., Lévesque C., Mèrand, Y. and Labrié, F. 1990. *Endocrinology* 126: 3223-3231). Medium was changed every other day in these experiments because of the slow reaction of the compound with an unknown component present in the IMEM and RPMI 1640 medium formulation.

Polyamine Analysis

ZR-75-1 cells were plated in 100 mm culture dishes at 5×10^5 cells/dish in MEZR medium and grown for 5 days with medium changes every other day. Fresh MEZR medium containing the indicated concentration of transport antagonist was then added, plus or minus 200 μ M cycloheximide (CHX), and cells were incubated for 1 or 6 hours. Medium was then removed, cell monolayers rinsed twice with 10 ml of ice-cold Ca²⁺/Mg²⁺-free phosphate buffered-saline (PBS) (2.7 mM KCl; 1.5 mM KH₂PO₄; 8.1 mM Na₂HPO₄; 137 mM NaCl), and harvested by centrifugation (2000 x g x 90 s at 4°C) following a 5- to 7- minute-incubation with bovine trypsin/EDTA solution (0.05%/0.02%, w/v) in Hanks' Balanced Salt Solution (Huber, M. and Poulin, R. 1995. *Cancer Res.* 55; 934-943). Cell pellets were resuspended in 300 μ l of 10% (v/v) trichloroacetic acid or Tris-DTT buffer (50 mM Tris/HCl, 0.1 mM EDTA, 5 mM DTT, pH 7.5) and stored at -20°C until further analysis. For chromatographic analysis, samples were first quickly thawed and incubated

THIS PAGE BLANK (USPTO)

for 15 minutes at 37°C. Trichloroacetic acid was then added to DTT-containing samples to a final concentration of 10% (wt/v). Samples were dispersed for 2 minutes in a sonicating water bath, and pelleted in a microcentrifuge for 5 minutes. The trichloroacetic acid-insoluble pellet was solubilized in 300-500 µl of 1 N NaOH and used to determine protein content using bovine serum albumin (fraction V) as standard. Polyamine contents were then analyzed by ion pair reverse-phase HPLC with fluorometric detection after postcolumn derivatization with *o*-phthaldialdehyde as described (Pegg, A.E., Wechter, R., Poulin, R., Waster, P.M., and Coward, J.K. 1989. *Biochemistry* **28**: 8446-8453; Huber, M., and Poulin, R. 1996. *Cancer Res.*, **55**: 934-943). In this system, putrescine, spermidine, spermine, MESC and DEASC were resolved with retention times of 18.5, 31.0, 35.0, 36.5, 37.5, and 44.0 minutes respectively.

DESC stability

DESC stability was tested by incubating the compound dissolved (at 50 µM) in PBS or in IMEM medium containing 10% (v/v) fetal bovine serum plus or minus 1 mM aminoguanidine in a humid 5% CO₂ atmosphere at 37°C and in the absence of cells. At indicated times, trichloroacetic acid was added to aliquots of this solution to a final concentration 10% (w/v) and the samples directly analyzed by HPLC as above.

Determination of Polyamine Uptake Activity

The rate of putrescine and spermidine transport was determined in ZR-75-1 cells incubated in serum-free RPMI 1640 medium as described (Lessard, M., Zhao, C., Singh, S.M. and Poulin, R. 1995. *J. Biol. Chem.* **270**: 1685-1694), using [³H]putrescine (30 Ci/mol) and [³H]spermidine (20 Ci/mol), respectively as substrates for a 20 minute-assay period. Spermine uptake was similarly determined, using 1 µM [¹⁴C]spermine (32 Ci/mol) as substrate. Uptake activity was expressed per amount of DNA as fluorometrically determined using 3,4-diaminobenzoic acid (Simard, J., Dauvois, S., Haagenzen, D.E., Lévesque, C., Mérand, Y. and Labrie, F. 1990. *Endocrinology*, **126**: 3223-3231). For the determination of spermidine uptake activity in CHO-K1 cells, 80% confluent cell monolayers were rinsed twice with PBS and incubated for 20 minutes at 37°C in 400 µl of buffer A (20 mM Tris-HCl, pH 7.4; 0.42 mM CaCl₂; 0.41 mM MgSO₄; 103 mM NaCl;

THIS PAGE BLANK (USPTO)

5.7 mM KCl; 1.1 mM D-glucose) containing 5 μ M [3 H]spermidine (20 Ci/mol). Cell cultures were then washed twice with 1 ml PBS containing 5.7 mM *sym*-norspermidine. Cells were then lysed with 200- μ l aliquot of 1 N NaOH and incubated for 30 minutes at 60°C. After neutralization with 200 μ l of 1 N HCl, radioactivity was determined from a 250- μ l of the cell lysate by scintillation counting. Uptake activity was expressed per amount of total cellular protein as determined by the method of Bradford (Bradford, M.M. 1976. *Anal. Biochem.* 72: 248-254). Non-specific binding of radioactive substrate was similarly determined in parallel for both cell lines after a 15 second-incubation with 400 μ l of ice-cold uptake solution.

Kinetic analyses

Kinetic analysis of polyamine transport was performed by determining uptake activity in the presence of a 3 μ M [3 H]putrescine or 1 μ M [3 H]spermidine plus increasing concentrations of nonradioactive substrate. K_m , K_i and V_{max} values were then estimated by Lineweaver-Burke analysis. For competitive inhibitors, K_i values were also estimated by measuring uptake activity in the presence of logarithmically increasing concentrations of antagonist, and using the Cheng-Prusoff equation (Cheng, Y.-C. and Prusoff, W.H. 1973. *Biochem. Pharmacol.* 22: 3099-3108) by iterative curve fitting for a sigmoidal curve. For mixed competitive/noncompetitive inhibition, two methods were used to calculate kinetic constants. First, the equation

$$V = \frac{V_{max}}{\frac{K_m}{S} \left(1 + \frac{I}{K_i} \right) + \left(1 + \frac{I}{K'_i} \right)}$$

where v , s , and i are the transport velocity, substrate concentration and inhibitor concentration respectively, was used to calculate the inhibition constants for inhibitor/carrier complex formation (K_i) and carrier/inhibitor/substrate complex formation (K'_i) (Dixon, M. and Webb, E.C. 1976. *Enzymes*, 3rd Ed., Academic Press, San Diego, CA). Alternatively, the value of K_i for a mixed competitor/non-competitor was estimated from the intersect of equations v^{-1} vs i at two different substrate concentrations (Dixon, M. and Webb, E.C. 1976. *Enzymes*, 3rd Ed., Academic Press, San Diego, CA).

THIS PAGE BLANK (USPTO)

Intracellular Accumulation

The time course of intracellular accumulation of spermidine in the presence of transport antagonists was determined by incubating ZR-75-1 cells in 24-well plates with DESC (50 or 200 μ M) or MESC (200 μ M) dissolved in MEZR medium containing 5 μ M [3 H]spermidine in the presence or absence of cycloheximide (CHX, 200 μ M), and harvesting at the indicated times for the determination of intracellular radioactive contents, as described above for polyamine uptake assays.

Statistical Analysis

Statistical significance of differences between means was assessed by unpaired Student's *t*-tests. Unless otherwise indicated, results are expressed as means \pm SD of determinations from triplicate cell cultures.

Design and Synthesis of DESC, DEASC and MESC

The original rationale for synthesizing MESC (Compound VII of Fig. 1) was to generate an affinity reagent with a thiol side chain that could be derivatized with fluorescent or radioactive sulfhydryl reagents to label the polyamine transporter. The precursor chosen for the synthesis, namely 5-carboxyspermine, has been previously used to prepare lipopolyamines for efficient DNA transfection (Behr, J.P. 1989. *J. Chem. Soc. Chem. Commun.* 101-103; Behr, J.P., Demeneix, B., Loeffler, J.-P. and Perez-Mutul, J. 1989. *Proc. Natl. Acad. Sci. USA* **86**: 6982-6986), and more recently, as a photoaffinity reagent to label the polyamine-binding site of casein kinase 2 (Leroy, D., Schmid, M., Behr, J.-P., Filhol, O., Pares, S., Garin, J., Bourgarit, J.-J., Chambaz, E.M. and Cochet, C. 1995 *J. Biol. Chem.* **270**: 17400-17406). The scheme used to prepare MESC involved the coupling of a cystamine bridge through amide bonds with two Boc-protected 5-carboxyspermine molecules to form DESC after removal of the Boc groups (Compound V of Fig. 1), followed by reduction of the DESC disulfide bridge. A small amount (10-15%) of the mixed MESC-cysteamine disulfide (DEASC, Compound VI; Fig. 1) was also generated in the coupling process. Complete separation of DEASC from DESC on a preparative basis proved to be difficult even using ion exchange chromatography (data not shown). Consequently, most DESC preparations contained a small amount (1-2%) of

THIS PAGE BLANK (USPTO)

DEASC after reversed-phase liquid chromatography on C_{18} silica gel. DESC and DEASC were stable for months in aqueous solutions buffered at pH=7.0, whereas MESC solutions were supplemented with DTT to prevent oxidation.

Affinity of DESC, DEASC and MESC for the Mammalian Diamine and Polyamine Transport

In order to evaluate the suitability of the spermine conjugates as prospective affinity ligands, their relative ability to inhibit putrescine and polyamine uptake was evaluated. As shown in Fig. 2, DESC was the most potent antagonist of [14 C]spermine transport in ZR-75-1 cells, with a K_i value about 5-fold and 16-fold lower than that of DEASC and MESC, respectively. The ability of spermine to compete against [3 H]putrescine and [3 H]spermidine uptake was in fact only about 7-fold higher than that of DESC (Fig. 3). DESC (Fig. 4A) and MESC (data not shown) were pure competitive inhibitors of [3 H]putrescine uptake at concentrations up to 100 and 200 μ M, respectively. On the other hand, inhibition of putrescine transport by DEASC belonged to a mixed competitive/non-competitive type (Fig. 4B). Table I summarizes the K_i values determined for DESC, MESC and DEASC toward putrescine, spermidine and/or spermine uptake, in relation with the mutual transport interactions between the latter substrates. Notably, K_i values of the three spermine conjugates with respect to putrescine uptake were 3-fold to 5-fold higher than for spermine uptake, unlike spermidine and spermine which both inhibited the uptake of either substrate with similar potency, and with a K_i roughly equal to their K_m as substrate.

TABLE I
 K_i Values of Inhibition of Diamine and Polyamine Transport by MESC, DESC and DEASC in ZR-75-1 Cells

Compound	K_m or K_i (μ M)		
	Putrescine	Spermidine	Spermine
Putrescine	3.7 ± 0.4^a	125 ± 29^a	$0.23 \pm 0.13^{a,b}$
Spermidine	0.23 ± 0.05^a	0.49 ± 0.15^a	0.37 ± 0.09^a
Spermine	0.33 ± 0.02^a	ND	0.20 ± 0.06^b

THIS PAGE BLANK (USPTO)

DESC	1.6 ± 0.5^b	2.7 ± 1.1^b	5.0 ± 0.7^b
MESC	22 ± 3^b	ND	80 ± 31^b
DEASC	$5.3 \pm 0.6 (K_i)^c$	ND	16 ± 3^d
	$4.1 \pm 0.5 (K_i')$		

Data annotated with *a* are from Lessard, M., Zhao, C., Singh, S.M., and Poulin, R. 1995. *J. Biol.*, **270**: 1685-1694, *b* indicates data obtained with this work; mean \pm SD of triplicate determinations from 2 to 4 different experiments; *c* corresponds to values of inhibition constants for carrier/inhibitor complex formation (K_i) and for carrier/inhibitor/putrescine complex formation (K_i') assuming a mixed competitive/non-competitive model; mean \pm SD of triplicate determinations at 3 three inhibitor concentrations at two different substrate concentrations for a series of increasing inhibitor concentrations (Dixon, M, and Webb, E.C. 1976. *Enzymes*, 3rd Ed., Academic Press, San Diego, CA).

The relative potency of DESC and MESC as competitive inhibitors of polyamine uptake was also evaluated in CHO-K1 cells, in which they respectively exhibited K_i values of 0.92 ± 0.15 and $33.6 \pm 7.2 \mu\text{M}$ (Fig. 5).

EXAMPLE 2

EFFECT OF SIDE CHAIN LENGTH AND SUBSTITUENTS ON SPERMIDINE TRANSPORT INHIBITION BY MESC DERIVATIVES

The observation that MESC was a less potent inhibitor of diamine and polyamine transport than DESC and DEASC suggested that the nature of the side chain strongly influences the interaction of these compounds with the carrier. The thiol side chain of MESC was thus derivatized with substituting groups of different sizes and charges through thioether linkage with three different iodoacetamides, namely LY iodoacetamide, ASIB and iodoacetamide itself, and the ability of the resulting complexes (MESC-LY, MESC-ASIB, and MESC-acetamide, respectively) to inhibit spermidine uptake was then evaluated. These studies were conducted using CHO-K1 cells. As shown in Fig. 5, derivatization of the thiol group of MESC did not significantly ($P > 0.10$) increase the K_i toward spermidine uptake for the three conjugates studied. In the case of MESC-ASIB, K_i values might have

THIS PAGE BLANK (USPTO)

been underestimated by partial inactivation of the polyamine carrier at the assay temperature, although the uptake reaction was conducted under subdued lighting. Thus, the results show that specific recognition of the spermine head of MESC can accommodate considerable variation in length, size, polarity or charge for the side chain without detrimental effect on its affinity for the polyamine carrier. Consequently, inhibitors having different side chains, while maintaining their inhibitory activity on polyamine transport are also encompassed by the present invention.

EXAMPLE 3
LACK OF PERMEATION OF DESC AND MESC
THROUGH THE POLYAMINE TRANSPORT SYSTEM

The ability of ZR-75-1 cells to accumulate DESC and MESC was determined. Since DESC was eluted as a late, broad peak in the HPLC system used, DTT was added to cell extracts to reduce DESC to MESC and decrease the detection threshold. Results are shown in Table II. ZR-75-1 cells were incubated for 1 or 8 hours in MEZR medium in the presence of 50 or 200 μ M DESC or MESC prior to determination of polyamine contents. CHX was added at 200 μ M where indicated. Other details are provided under "Materials and Methods." Values are the mean \pm SD of triplicate determinations from 2 independent experiments.

THIS PAGE BLANK (USPTO)

TABLE II
Intracellular Accumulation of DESC and MESC in ZR-75-1 Cells

		Polyamine intracellular contents (nmol/mg protein)				
	Addition	Time (h)	Spermidine	Spermine	DESC	MESC
5	Control	1	0.69 ± 0.08	8.22 ± 0.48	-	-
		6	0.91 ± 0.07 ^a	9.16 ± 0.13	-	-

		6	0.81 ± 0.15	8.32 ± 0.43	<0.01	0.13 ± 0.06

^a Significantly different ($P < 0.5$) from control value at time = 1h. (?)

As shown in Table II, only trace amounts of DESC could be recovered in ZR-75-1 cells after a 6-hour incubation with 200 µM DESC, but not with 50 µM; DESC could be detected only after reduction with DTT. These levels represent only about 1.5% of the accumulation measured in ZR-75-1 cells under identical conditions for spermine (Lessard, M., Zhao, C., Singh, S.M. and Poulin, R., 1995. J. Biol. Chem. 270: 1685-1694). Moreover, inhibition of protein synthesis by cycloheximide (CHX), which is known to upregulate polyamine uptake by preventing the synthesis of a polyamine-induced feedback repressor of transport (Lessard, M., Zhao, C., Singh, S.M. and Poulin, R. 1995. J. Biol. Chem. 270: 1685-1694; Mitchell, J.L.A., Diveley, R.R., Jr. and Bareyal-Leyser, A. 1992. Biochem. Biophys. Res. Commun. 186: 81-88), did not enhance DESC internalization, in marked contrast with its effect on spermidine accumulation under similar conditions (Fig. 6B) (Lessard, B., Zhao, C., Singh, S.M. and Poulin, R., 1995. J. Biol. Chem. 270: 1685-1694). Likewise, MESC was accumulated to measurable levels by ZR-75-1 cells only

THIS PAGE BLANK (USPTO)

when present at 200 μ M (cf. Table II). Thus, neither DESC or MESC appear to be used as substrates for the polyamine transport system despite the high affinity of the former compound as an antagonist of diamine and polyamine uptake.

EXAMPLE 4
EFFECT OF DESC AND MESC ON
INTRACELLULAR POLYAMINE ACCUMULATION

The time course of internalization of radio-labeled spermidine was determined in ZR-75-1 cells incubated for up to 6 hours in the presence of the impermeant agonists. As illustrated in Fig. 6A, steady-state [3 H]spermidine accumulation in the absence of competitor abruptly reached a near plateau after about 1 hour, which results from the induction of feedback inhibition of polyamine transport (Lessard, M., Zhao, C., Singh, S.M. and Poulin, R., 1995. *J. Biol. Chem.* **270**: 1685-1694). MESC and DESC decreased the initial rate of spermidine uptake according to their respective potency as competitive antagonists. Interestingly, spermidine accumulation in the presence of either inhibitor followed a pattern similar to that of control cells, i.e. a rapid phase during the first 60 minutes, followed by a much slower rate of accumulation thereafter, which was nearly independent of antagonist concentration. This pattern suggests that even cellular levels of newly internalized spermidine as low as 20% of those found under control conditions, e.g., in cells treated with 200 μ M DESC, may induce a near maximal degree of feedback repression of polyamine transport. Nevertheless, even a 40-fold excess of the most potent antagonist (i.e. 200 μ M DESC) only decreased net spermidine accumulation by only 50% after 6 hours. As previously observed ((Lessard, M., Zhao, C., Singh, S.M. and Poulin, R., 1995. *J. Biol. Chem.* **270**: 1685-1694), CHX abolished the induction of feedback transport inhibition, resulting in a 4-fold increase in spermidine accumulation after 4 hours (Fig. 6B). Protein synthesis inhibition also enhanced spermidine accumulation in DESC-treated cells, a finding consistent with the onset of substantial feedback transport repression by subthreshold levels of internalized substrate. Thus, in the absence of the feedback mechanism, the highest concentration of DESC tested (200 μ M) decreased net [3 H]spermidine accumulation by 80 to 85% after 6 hours and to a level lower than that found in control cells with a fully repressed uptake activity.

THIS PAGE BLANK (USPTO)

EXAMPLE 5
EFFECT OF DESC, DEASC AND MESC
ON CELL PROLIFERATION

5 Due to the analogy of the novel transport antagonists with spermine, it might be
surmised that they would exhibit significant cytotoxicity like the parent molecule. The
marked toxicity of low ($<10^{-3}$ M) spermine concentrations in biological media mostly results
from catabolism by copper amine oxidases, which generates a dialdehyde, acrolein and
H₂O₂ as deleterious products and can be irreversibly inhibited by carbonyl reagents such
10 as aminoguanidine (Morgan, D.M.L. 1989. in *The Physiology of Polyamines* (Bachrach,
U., and Heimer, Y.M. eds) Vol. I, pp. 203-229, CRC Press, Boca Raton). The
biocompatibility of DESC, MESC, and DEASC was thus evaluated during a long-term (11-
day) incubation with ZR-75-1 cells grown in RPMI 1640 containing 10% (v/v) FBS in the
absence and presence of 1 mM aminoguanidine. As shown in Fig. 7, aminoguanidine alone
15 had a slight inhibitory effect on ZR-75-1 cell growth as previously observed (Huber, M.
and Poulin, R. 1995. *Cancer Res.* 55: 934-943). Although DESC was only mildly growth
inhibitory at 50 μ M, there was an abrupt, aminoguanidine-resistant increase in toxicity at
200 μ M. In contrast, spermine was acutely cytotoxic at 50 μ M, an effect that was only
partly prevented by aminoguanidine. MESC was considerably less toxic than its dimer,
20 with a 35% decrease in cell growth at 200 μ M which was not blocked by aminoguanidine.
On the other hand, 50 μ M DEASC caused a 20% inhibition of cell proliferation which
could be completely prevented by the amine oxidase inhibitor. Thus, DESC, and to a much
lesser degree, its thiol monomer MESC, are cytotoxic toward breast cancer cells at high
concentrations through a mechanism that does not involve BSAO. Weak growth inhibition
25 caused by the mixed MESC-cysteamine disulfide, however, apparently involved
degradation by a copper amine oxidase.

EXAMPLE 6
EFFECT OF DESC ON RESCUE OF DFMO-INDUCED
30 **GROWTH INHIBITION BY EXOGENOUS SPERMIDINE**

Although DESC is indeed a potent antagonist of polyamine accumulation, the slow
residual uptake that occurred even at a 40-fold molar excess of inhibitor might be sufficient
to counteract polyamine depletion by inhibitors of polyamine biosynthesis. This possibility

THIS PAGE BLANK (USPTO)

was assessed by comparing the ability of DESC to prevent the reversal of DFMO-induced growth inhibition by increasing concentrations of exogenous spermidine. At concentrations superior to 0.3 μ M, spermidine inhibited ZR-75-1 cell proliferation by up to 20% (Fig. 8). This effect could be due to an incomplete inhibition of BSAO by aminoguanidine (Seiler, N. 1987. in *Inhibition of Polyamine Metabolism. Biological Significance and Basis for New Therapies* (McCann, P.P., Pegg, A.E. and Sjoerdsma, A. eds.), pp. 49-77, Academic Press, Orlando), since it was not observed in media supplemented with equine serum, which does not contain amine oxidase activity (Blaschko, H. and Hawes, R. 1959. *J. Physiol.* 145: 124-131), instead of FBS (data not shown). The approximately 50% growth inhibition induced by 1 mM DFMO after an 11-day incubation was completely reversed by as little as 0.3 μ M spermidine, whereas 0.1 μ M spermidine already restored growth of DFMO-treated cells to 78% of control value. However, addition of 50 μ M DESC was unable to prevent the reversal of DFMO-induced growth inhibition by spermidine, even at a DESC:spermidine ratio of 500. Essentially similar results were obtained using horse serum instead of FBS, or replacing RPMI 1640 medium, which contains 3.2 μ M reduced glutathione that might undergo thiol/disulfide exchange with DESC, with thiol-free IMEM (data not shown).

EXAMPLE 7 **STABILITY OF DESC IN BIOLOGICAL MEDIA**

The inability of DESC to block the biological effect of exogenous spermidine, even when present at large molar excesses, might have been caused by its degradation in growth media. To assess this hypothesis, DESC solutions (20 μ M) made in PBS or in sterile IMEM medium enriched with 10% (v/v) FBS were incubated for 20 minutes or 48 hours under cell-free conditions at 37°C in a humid 5% CO₂ atmosphere, and the polyamine analog was then analyzed by ion-pair reversed-phase HPLC. After 48 hours, degradation of DESC to two new amine-containing derivatives occurred in IMEM (Fig. 9A, B) but not in PBS (Fig. 9C), as evidenced by the appearance of a major (compound 1) and minor (compound 2) peaks of *o*-phthaldialdehyde-reactive material eluting earlier than DESC. Although aminoguanidine did not prevent DESC degradation to the two unknown products, it did prevent the degradation of a trace amount of DEASC (indicated as compound 3) initially present in the DESC preparations, thus confirming that DEASC can indeed be a

THIS PAGE BLANK (USPTO)

substrate of serum copper amine oxidase (Fig. 7). MESC could not be detected, indicating that DESC does not undergo reduction to MESC under conditions used for cell culture. Furthermore, the decomposition of DESC in IMEM showed an identical pattern in the presence or absence of FBS, which thus ruled out a serum component as being responsible for the degradation. Figure 10 shows that DESC was slowly degraded to compounds 1 and 2. After 48 hours, i.e. the interval at which freshly made DESC-containing media were added to cell cultures in growth experiments, 40% of the DESC originally present had been decomposed by IMEM. Identical results were obtained using RPMI 1640 medium instead of IMEM. Thus, the present inventors propose that a component present in IMEM and RPMI 1640 medium, but not in PBS, must be responsible for the degradation of DESC.

DESC, a novel type of spermine derivative, is shown to be endowed with high affinity for the polyamine transport system while being highly resistant to cellular uptake. The combination of these two attributes confers unique characteristics to DESC as a pure competitive antagonist of polyamine uptake.

As compared with spermine, the higher K_i of MESC against putrescine, spermidine and spermine uptake could owe to the presence of an amide linkage, which decreases the basicity of the neighboring secondary amino group of the spermine head ($pK_a = 5.5$ in comparison with 8.9-9.8 for spermine) (Tabor, C.W. and Tabor, H. 1984. *Ann. Rev. Biochem.* 53: 749-790; Remy, J.-S., Kichler, A., Mordvinov, V., Schuber, F. and Behr, J.-P. 1995. *Proc. Natl. Acad. Sci. USA* 92: 1744-1748, and/or may cause steric hindrance for its interaction with the polyamine binding site (Bergeron, R.J. and Seligsohn, H.W. 1986. *Bioinorg. Chem.* 14: 345-355; Porter, C.W., Cavanaugh, P.F., Jr., Stolowich, N., Ganis, B., Kelly, E., and Bergeron, R.J. 1985. *Cancer Res.* 45: 2050-2057). Despite the particular structural features of MESC as a ligand, its dimerization into DESC increased by up to 20-fold the affinity of the resulting structure for the polyamine transporter. There is no precedent for dimeric polyamine structures like DESC. Its overall design is reminiscent of that of 2-N-4-(1-azi-2,2,2-tri-fluoroethyl)benzoyl-1,3-bis(D-mannos-4-yloxy)-2-propylamine, an impermeant ligand which binds to the exofacial domain of facilitative glucose transporters and bears two symmetrical sugar moieties linked tail to tail (Clark, A.E. and Holman, G.D. 1990. *Biochem. J.* 269: 615-622). At least one mammalian glucose transporter, namely GLUT-1, exists as a tetrameric complex in its native form (Hebert,

THIS PAGE BLANK (USPTO)

D.N. and Carruthers, A. 1992. *J. Biol. Chem.* **267**: 23829-23838; Gould, G.W. and Holman, G.D. 1993, *Biochem. J.* **295**: 329-341). The stronger affinity of DESC relative to MESC could reflect a dyad symmetry in the organization of the transporter complex. Alternatively, dimerization of MESC into DESC could impose conformational constraints (e.g. due to electrostatic repulsion) that would favor recognition of the polyamine binding site of the carrier by each of the symmetrical spermine moieties.

MESC thioethers as diverse in size as MESC-LY, MESC-ASIB, or MESC-acetamide had K_i values virtually identical to that of MESC, indicating that the thiol group of MESC does not specifically determine its lower affinity as a polyamine transport inhibitor as compared with DESC. These data suggest that additional bulk on the side chain has little influence on the interaction of MESC with the polyamine transporter, in agreement with the observation that large substituents attached to the distal end of a spacer of sufficient length do not notably decrease the affinity of spermidine as a substrate for uptake (Holley, J.O., Mather, A., Wheelhouse, R.T., Cullis, P.M., Hartley, J.A., Bingham, J.P., and Cohen, G.M. 1992. *Cancer Res.*, **52**: 4190-4195). Unexpectedly, the MESC-cysteamine mixed disulfide (DEASC) was found to block putrescine uptake as a mixed competitor/non-competitor, whereas MESC and DESC behaved like pure competitive inhibitors of putrescine transport. Since the interaction of DESC or MESC with the polyamine transporter was strictly competitive, and because DEASC exhibits higher affinity than MESC as an inhibitor of diamine and polyamine transport, the spermine head and the cysteamine side chain of DEASC might be respectively responsible for the competitive and non-competitive components of its transport inhibition.

The biochemical properties of DESC clearly illustrate that the binding affinity of a compound can be dissociated from its ability to serve as a substrate for the polyamine transporter. The large size of DESC cannot be the main factor preventing its internalization through the channel-like portion of the transporter since MESC was also virtually impermeant. Thus, the mere attachment of an amido side chain on the spermine backbone would appear to be responsible *per se* for the impaired internalization of MESC and its derivatives. Indeed, N^4 -alkylated spermidine derivatives are far better competitors of spermidine uptake than their N^4 -acyl counterparts in mouse leukemia cells, in support of the notion that charged secondary amino groups are important in the interaction with the

THIS PAGE BLANK (USPTO)

polyamine carrier (Porter, C.W., Cavanaugh, P.F., Jr., Stolowich, N., Ganis, B., Kelly, E., and Bergeron, R.J. 1985. *Cancer Res.* 45: 2050-2057). However, the latter argument cannot account for the fact that long-chain aliphatic α , ω -diamines with at least 6 to 7 methylene groups have an affinity comparable to that of spermidine (Lessard, M., Zhao, C., Singh, S.M. and Poulin, R., 1995. *J. Biol. Chem.* 270: 1685-1694, Bergeron, R.J. and Seligson, H.W. 1986. *Bioinorg. Chem.* 14: 345-355; Porter, C.W. and Bergeron, R.J. 1983. *Science* 219: 1083-1085; Minchin, R.F., Martin, R.L., Summers, L.A. and Ilett, K.F., 1989. *Biochem. J.* 262: 391-395; Gordonsmith, R.H., Brooke-Taylor, S., Smith, L.L. and Cohen, G.M. 1983. *Biochem. Pharmacol.* 32: 3701-3709). A more likely explanation for the poor affinity of polyamines bearing an acyl side chain might be the steric hindrance due to the amide group, which restricts the freedom of rotation around the adjacent carbon and nitrogen atoms. There are indications that cyclic or pseudocyclic conformations of polyamines stabilized by hydrogen bonds might be energetically favored for recognition and/or internalization of substrates of the polyamine transport system (Lessard, M., Zhao, C., Singh, S.M. and Poulin, R., 1995. *J. Biol. Chem.* 270: 1685-1694; Bergeron, R.J. and Seligsohn, H.W. 1986. *Bioinorg. Chem.* 14: 345-355). The formation of such folded conformers would be impaired by the presence of an amide group next to the polyamine chain. In support of this hypothesis, chlorambucil-spermidine, which bears a N-propyl chlorambucil carboxamide side chain on the central nitrogen of spermidine, is a good substrate of the polyamine transport system, with a K_m averaging that of spermidine (Holley, J.L., Mather, A., Wheelhouse, R.T, Cullis, P.M., Hartley, J.A., Bingham, J.P., and Cohen, G.M. 1992. *Cancer Res.* 52: 4190-4195). In marked contrast, a spermidine conjugate with a chlorambucil carboxamide side chain directly attached at the C5 position of the spermidine head is a very poor substrate of the polyamine uptake system (Stark, P.A., Thrall, B.D., Meadows, G.G., and Abdel-Monam, M.M. 1992. *J. Med. Chem.* 35: 4264-4269).

Although a 40-fold molar excess of DESC dramatically reduced the rate of spermidine uptake in ZR-75-1 cells, slow but continuous spermidine accumulation was still observed in the presence of the inhibitor. The low rate of polyamine internalization observed even in the presence of a large excess of DESC, in addition to the slow

THIS PAGE BLANK (USPTO)

decomposition of the inhibitor, may largely explain the complete inability of DESC to prevent polyamine-mediated prevention of growth inhibition by DFMO.

Since the affinity of MESC thioethers remains virtually unaffected relative to the unconjugated polyamine, MESC-ASIB might serve as a photoaffinity label to detect polyamine-binding proteins, including the polyamine carrier. Experiments are currently conducted with ¹²⁵I-labeled MESC-ASIB to assess its usefulness as a probe to identify the mammalian polyamine transporter. A recent report has described the specific labeling of discrete plasma membrane proteins using ¹²⁵I-labeled *N*¹-azidosalicylamido-norspermine and *N*⁴-azido-salicylamidoethylspermidine as photoaffinity reagents (Felschow, D.M., MacDiarmid, J., Bardos, T., Wu, R., Woster, P.M. and Porter, C.W. 1995. *J. Biol. Chem.* 270: 28705-28711). However, these conjugates are internalized by mammalian cells (Felschow, D.M., MacDiarmid, J., Bardos, T., Wu, R., Woster, P.M. and Porter, C.W. 1995. *J. Biol. Chem.* 270: 28705-28711), and MESC-ASIB or similar derivatives could be useful as a photoactivatable probes to exclude labeling of intracellular proteins.

While not intending to be limited to any particular theory, the slow degradation of DESC observed in growth media, but not in PBS, was likely due to L-cystine, which is present at 100 and 200 μM in IMEM or RPMI 1640 medium, respectively, through the formation of mixed disulfides with DESC. Nevertheless, the cytotoxicity of high concentrations of DESC and MESC is unlikely to be solely due to the formation of such adducts, since MESC was less toxic than DESC, despite the fact that the free thiol group of the former would make it more reactive toward L-cystine]. The present data clearly show that DESC has remarkably low toxicity in comparison with its homolog spermine. Thus, the basic features of this molecule, including its resistance to BSAO, should be useful for the design of potent transport inhibitors with minor non-specific effects on cell viability. The inherent structural features of DESC that confer its high affinity and resistance to uptake should thus provide a useful framework for the design of potent irreversible inhibitors of polyamine transport, which could incorporate an alkylating group such as that used in the design of specific suicide substrates of mammalian glucose transporters (Clark, A.E., and Holman, G.D. 1990. *Biochem. J.* 269: 615-622; Lehmann, J., and Scheuring, M. 1995. *Carbohydrate Res.* 276: 57-74)].

THIS PAGE BLANK (USPTO)

Polyamine derivatives (natural or synthetic) comprising sulfur in the side chain have been made, because they conducted to the formation of dimers simply by forming a disulfide bridge. By-products which are not dimers have also shown an activity. However, it will be readily apparent to those skilled in the art that compounds being more stable than those containing sulfur atoms are contemplated. Therefore, the side chains used for increasing the affinity of the derivatives for a polyamine transporter and/or as substrates for labeling molecules and/or as a spacer in the making of a dimer can be varied to optimize the characteristics of the derivatives of the present invention.

Any equivalent structures or modifications obtainable without departing from the teachings and the spirit of this invention are considered as part of the scope thereof because the invention is in no way limited to the particularly disclosed embodiments, as reflected in the appended claims.

EXAMPLE 8

SYNTHESIS AND EVALUATION OF SPERMINE DIMERS AS INHIBITORS OF POLYAMINE TRANSPORT AND ENHANCERS OF EFLORNITHINE ACTION IN TUMOR CELLS AND TUMOR-BEARING ANIMALS

Novel spermine analogs will be synthesized and evaluated as blockers of transport in tumor cells simultaneously treated with D,L- α -difluoromethylornithine (DFMO = Eflornithine). These molecules are based on the overall design of a prototype, 2, 2'-dithiobis(*N*-ethyl-spermine-5-carboxamide) (DESC). DESC has recently been reported to act as a competitive and potent antagonist of polyamine uptake in leukemia and breast cancer cells. DESC is proposed here to potentiate the chemotherapeutic efficacy of DFMO. While not intending to be limited to any particular theory, it is proposed that such effect is provided by preventing the replenishment of DFMO-treated tumor cells with polyamines from exogenous sources. Structural modifications to the molecule will improve it to a pharmacologically useful compound. These modifications include: [i] the replacement of the disulfide bridge with a fully reduced aliphatic chain to prevent its rapid reaction with biological thiols and disulfides and [ii] the addition of substituents to prevent its oxidative deamination by the ubiquitous plasma enzyme, serum amine oxidase.

Two types of DESC analogs will be synthesized, and characterized for their ability to inhibit polyamine transport and to enhance the therapeutic action of DFMO in various

THIS PAGE BLANK (USPTO)

tumor cell types, including animal models. The first type of analogs will be simply obtained by substituting the original cystamine side chain of DESC with α,ω -diamine cross-linkers of varying length. The synthesis of these analogs will help in the short term to optimize the length of the cross-linker chain, and to rapidly evaluate their relative ability to potentiate DFMO action *in vitro*. The second type of analogs will be made according to a new route of synthesis to introduce methyl groups at the extremities of the spermine-like backbone, and will also incorporate alkylation instead of acylation of the aliphatic, α,ω -diamine cross-linker in order to improve their affinity for the polyamine transport system, their potency as antagonists of uptake and as enhancers of DFMO therapeutic action. The pharmacological evaluation of the second-type analogs will be conducted in a standard mouse model bearing L1210 leukemia tumor cells treated with DFMO.

2,2'-dithiobis (*N*-ethyl-spermine-5-carboxamide) (DESC) and its thiol monomer, *N*-(2-mercaptoethyl) spermine 5-carboxamide (MESC) (Fig. 11) have been synthesized as precursors of photoaffinity labeling probes of polyamine-binding proteins (21). Characterization of the potency of DESC and MESC to inhibit polyamine transport unexpectedly showed that DESC has ≈ 20 -fold higher affinity than MESC for the polyamine carrier. The marked difference in transport inhibitory potency between MESC and its dimer suggested that the carrier protein might have a dyadic symmetry, and that the conjugation of two spermine molecules through a cross-linking side chain could markedly enhance the interaction with the polyamine transporter. Moreover, neither DESC nor MESC is significantly internalized by human breast cancer cells or mouse leukemia cells at concentrations that saturate the polyamine carrier, indicating that they are essentially membrane-impermeant (21). The combination of high affinity and lack of carrier-mediated permeation of DESC provided the basis for a novel design of pure polyamine transport antagonists that could be used in combination with DFMO to enhance polyamine depletion in tumor cells exposed to physiological levels of exogenous polyamines.

DESC was designed for biochemical use. It was found to be degraded in physiological media due to thiol-disulfide reaction with compounds such as L-cystine. DESC cannot efficiently counteract the ability of exogenous spermidine to reverse DFMO-induced cytostasis in breast cancer cells as a result of this instability (21). DESC is also subject to attack by serum amine oxidase (SAO), an ubiquitous plasma enzyme which oxidatively

THIS PAGE BLANK (USPTO)

deaminates aminopropyl groups, albeit to a much lesser degree than the parent compound, spermine. Modifications that further improve the design of DESC analogs that are part of particular embodiments of the present invention are:

(1) To use chemically inert, aliphatic diamines as cross-linkers to conjugate two spermine-like moieties; and/or

(2) To introduce methyl groups on the terminal carbons of the spermine-like backbones of the molecule. This latter modification will prevent/reduce the oxidation of spermine by SAO.

8.2) Synthesis and biochemical evaluation of unmethylated, stable DESC analogs

DESC analogs are prepared with unmodified spermine backbones but different side chain lengths as lead compounds to guide us in the design of methylated analogs described herein. This series of compounds will be synthesized in order to:

(i) Perform a structure-function study in the short-term to determine the optimal length of the cross-linker for inhibition of polyamine uptake.

Compounds VIIIA to VIIID (Fig. 12) will be rapidly available in amounts sufficient for *in vitro* testing. A refinement to the originally proposed route of synthesis will be the use of Fmoc-blocked diamine precursors. One such diamine precursor is $\text{NH}_2(\text{CH}_2)_n\text{NH}_2$ where $n = 3$ to 6. Instead of simultaneously coupling two spermine-like moieties to a diamine cross-linker, each amino group of the diamine cross-linker was sequentially amidated to the spermine-like precursor with the *N*-Fmoc-diamine, and then the other amine group was deprotected for the second amidation reaction. This sequential reaction scheme improves the purification of the spermine dimer from the spermine monoamide. This was difficult to achieve with the original method. The present method will improve the yield of desired product through a better control of the reaction stoichiometry.

The kinetic properties of these DESC analogs (abbreviated as BS-3, BS-4, BS-5 and BS-6; Fig. 12), as inhibitors of polyamine transport will be determined by uptake assays of radiolabeled putrescine, spermidine and spermine, according to procedures in Huber et al. (1996), J. Biol. Chem., 271: 27556-27563, which is specifically incorporated herein by reference. These structures are shown below.

THIS PAGE BLANK (USPTO)

wherein n is 3, 4, 5 or 6.

(ii) Use of analogs to potentiate the effect of DFMO in the presence of exogenous polyamines, which is the main criterion of pharmacological activity for polyamine transport inhibitors.

These compounds are expected to be stable under cell culture conditions in the presence of aminoguanidine, a SAO inhibitor (13, 28, 40, 46, 49, 66, 67). These polyamine transport inhibitors will be evaluated using ZR-75-1 human breast cancer cells and L1210 mouse leukemia cells. Briefly, the rate of cell proliferation will be determined in ZR-75-1 and L1210 cells grown in the presence or absence of DFMO (1 and 5 mM, respectively), and of the transport inhibitor candidate to be analyzed, in the presence of increasing concentrations of putrescine or spermidine. The ability of the transport antagonist to prevent the reversal of DFMO-induced growth inhibition by exogenous putrescine or spermidine will provide a valid measurement of the pharmacological potential of these compounds as enhancers of DFMO action *in vivo*. These studies will also include (a) dose-response experiments to evaluate the cytotoxicity of these analogs and the optimal concentration for their use as inhibitors of polyamine uptake, and (b) measurement of the uptake of the transport inhibitors during incubation with tumor cells by HPLC, along with their effect on polyamine pools.

Since the latter type of inhibitors will rapidly provide the first stable DESC analogs available, the thorough analysis of their biological properties with cultured tumor cells will be important to validate the concept of spermine dimers as polyamine transport blockers. Moreover, the structure-function relationships of this series will help in refining the design of the methylated analogs described in the following section.

THIS PAGE BLANK (USPTO)

8.3) Design, synthesis and evaluation of oxidation-resistant, stable methylated DESC analogs

While replacing the nature of the cross-linking chain is a rather straightforward modification, the second alteration required considerable changes in the preparation scheme originally used for DESC synthesis. The reduction step proposed to obtain a 1,12-dimethylspermine 5-carboxyl methyl ester from a 1,4-bis(3-azidobutyramido) ornithine methyl ester (Fig. 13, XIII) could not spare the ester group, resulting instead into the formation of 1,12-dimethylspermine 5-carbinol (Fig. 3, XIV). Changing the nature of the ester group did not improve the synthesis since steric hindrance problems prevented amidation of the amino groups of ornithine methyl ester the most proximal to the ester group. The nature of the proposed precursor was modified, and two 1,12-dimethylspermine 5-methyl chains were conjugated to an α,ω -diamine cross-linker through alkylation rather than through amide bonds (Figs. 14 to 16). This modification represents an improvement over the original design, since direct alkylation will lead to compounds with a higher affinity for the polyamine transporter - and higher potency as transport antagonists - as compared with the more rigid acylated analogs, as previously shown for spermidine analogs (8, 19, 44, 52, 54, 56). The proposed scheme of synthesis, for which steps IX to XIV have already been realized, is provided in Figs. 13 to 16. This improved scheme also includes the use of mono-FMOC-protected diamines as building blocks for cross-linking the dimethylspermine-5-methyl precursors, as described above for the unmethylated DESC analogs. The resulting compounds are abbreviated as BMS-3, BMS-4, BMS-5 and BMS-6 (Fig. 16; compounds XXa to Xxd).

THIS PAGE BLANK (USPTO)

wherein n is 3, 4, 5 or 6.

The *in vitro* evaluation of this series will be conducted for the unmethylated DESC analogs. The effectiveness of a combination of polyamine depletion with the selected PA transport antagonist as an antitumor strategy will then be assessed *in vivo*. For this purpose, an established experimental cancer model, namely L1210 mouse leukemia, will be used to evaluate the therapeutic potential of the candidate transport inhibitor. This leukemia model is an aggressive tumor type with a median host survival time of 9 days in the absence of treatment. Moreover, it is completely resistant to DFMO as a single tumor agent *in vivo* (albeit very sensitive *in vitro*), whereas PA transport deficiency and/or reduction of exogenous PA sources confers a striking ability to DFMO to extend survival rates, with complete cure being observed in $\geq 75\%$ of animals (1, 50).

Protocol 1 - Toxicity will first be determined by single i.v. and i.p. injections of logarithmically increasing drug concentrations to mice and estimating the LD₅₀. Blood samples will be taken at intervals to measure the plasma drug concentration by ion pairing reverse-phase HPLC (22, 23). Body weight and liquid consumption will also be monitored for 10 days, at the end of which period animals will be sacrificed to evaluate the incidence of liver and kidney damage. A similar experiment will be conducted by dissolving the drug in the drinking water with free access to the animals.

Protocol 2 - On day 0, mice will be injected with L1210 cells, with concomitant treatment with DFMO or vehicle, plus or minus 2 different sublethal doses of the transport antagonist on a daily schedule. Oral, i.v. and i.p. routes will be compared for the transport antagonist. Survival will be evaluated for up to 120 days, with regular body weight measurements and blood sampling to determine the steady-state plasma concentrations of inhibitor. L1210 cells are strongly immunogenic tumors and cured animals develop extended immunity against this leukemia (1). Thus, to evaluate the curative potential of the drug combination, survivors will be rechallenged with L1210 cells in the absence of treatment and survival monitored.

THIS PAGE BLANK (USPTO)

EXAMPLE 9

The present example demonstrates the utility of the present invention with the use of compounds that are analogs of spermine that include two chains connected to one another through a linker. The linker molecule that attaches the two spermine chains may be any spacer chain that is capable of bridging the polyamine chains.

The two chains may attach to the linker at an internal C atom or an N group within the chain. It is also possible for one chain to be connected to the linker through one of its carbon molecules, while the second chain attaches to the linker molecule through an N group within its chain.

The general structure of compounds claimed include the following characteristics:

(1) The central carbon chain of the spermine backbone can have between 3 and 7 methylene groups or carbon atoms. This is the range of central chain length that can be accommodated with good affinity by the mammalian polyamine transporter (81).

(2) Each methylene group of the polyamine chains can be modified by methyl groups without compromising the ability of the inhibitor to interact with the polyamine transporter.

(3) The linkage between the polyamine chains and the spacer may comprise any type of linkage compatible with a $K_i \leq 20\mu\text{M}$ (relative to spermine) for the resulting inhibitor, such as direct alkyl substitution or ether group on the central methylene groups (Structure 1), or alkylation on the secondary amino (Structure 2) groups of the polyamine chain.

Structure 1

THIS PAGE BLANK (USPTO)

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than two and less than five ($2 < x < 5$), and the sum of $y+z$ is greater than or equal to 2 and less than or equal to 6 ($2 \leq y+z \leq 6$). $R_3 = \text{CH}_2, \text{S}, \text{C=O}$ or NH ; $2 < x < 5$; $2 \leq y+z \leq 6$; L = a chemical structure (the linker) connecting covalently the two polyamine chains via alkyl, amide, ether or thioether bonds with a substituent group (R_3) attached on a carbon atom located between the two most internal amino groups of the polyamine chain.

Structure 2

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than two and less than five ($2 < x < 5$), w is greater than 2 and less than 8 ($2 < w < 8$) and the sum of $y+z$ is greater than or equal to 2 and less than or equal to 6 ($2 \leq y+z \leq 6$).

The invention when a carbon of one chain is attached by a linker to the nitrogen of a second chain is represented in Structure 3.

Structure 3

THIS PAGE BLANK (USPTO)

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than two and less than five ($2 < x < 5$), w is greater than 2 and less than 8 ($2 < w < 8$) and the sum of $y+z$ is greater than or equal to 2 and less than or equal to 6 ($2 \leq y+z \leq 6$). $R_3 = \text{CH}_2, \text{S}, \text{C=O}$ or NH ; $2 < x < 5$; $2 \leq y + z \leq 6$; L = a chemical structure (the linker) connecting covalently the two polyamine chains via alkyl, amide, ether or thioether bonds with a substituent group (R_3) attached on a carbon atom located between the two most internal amino groups of the polyamine chain.

Alkylation can be preferred over amidation because the former allows a greater flexibility to the polyamine chain to adopt the optimal conformation to interact with the polyamine transporter (81).

(4) The Linker (L) can be of any nature or chain length, as long as the total mass of the final structure does not exceed 3,000. These molecules may in other embodiments be described as having a total mass of between about 50 to about 2,500, or about between 500 to about 1500 or about 1,000 as a total mass. By way of example, such linkers may comprise alkyl, ether, a thioether, amide, phosphono, keto, amine, or sulfonyl groups or a combination thereof.

The linker may comprise a carbon chain by a length of 2 to 50 carbons.

In some embodiments, the carbon chain will have a length of between 5 to about 25 carbons, or between 10 and 20 carbons, or in even other embodiments, the carbon length of 2 to about 15 or 12 carbons.

EXAMPLE 10 **DIMERIC SPERMIDINE DIMERS AS** **POLYAMINE TRANSPORT INHIBITORS**

In another family of synthetic derivatives of original polyamines, the synthetic original polyamine is either *sym*-norspermidine, *sym*-homospermidine, or spermidine, and is cross linked to a second original polyamine by a side group on the central amino group of said polyamines.

Various examples of such molecules, which by no means include all embodiments made possible by this alternative design, are (A) spermidine dimers cross-linked by an α, α' -dialkyl disulfide side chain via *N*-alkyl bonds with the central amino group of each triamine chain as depicted for type compound I, *N,N'*-bis(3-aminopropyl), *N,N'*-bis(4-aminobutyl)cystamine or BABAC (structure I, Fig. 25), (B) *sym*-norspermidine dimers

THIS PAGE BLANK (USPTO)

[BNSpd-(n+2), structure II, Fig. 25] or spermidine dimers [BSpd-(n+2), structure III, Fig. 25] cross-linked by an aliphatic chain with $n+2$ methylene groups ($0 < n < 8$) via *N*-alkyl bonds with the central amino group of each triamine chain, (C) *sym*-norspermidine dimers cross-linked by an aryl-containing side chain via *N*-alkyl bonds with the central amino group of each triamine chain as depicted for type compound IV, *N,N,N',N'*-tetrakis(3-aminopropyl)-*p*-xylylenediamine or TADAX (structure IV, Fig. 25), or their *sym*-homospermidine and spermidine-like homologs (not illustrated), (D) *sym*-homospermidine, *sym*-norspermidine or spermidine dimers cross-linked by an alkene side chain via *N*-alkyl bonds with the central amino group of each triamine chain with either a *trans* (BABA-*trans*, structure V, Fig. 26) or a *cis* configuration around the single double bond (BABA-*cis*, structure VI, Fig. 26), and (E) *sym*-homospermidine, *sym*-norspermidine or spermidine dimers cross-linked by an alkyne side chain via *N*-alkyl bonds with the central amino group of each triamine chain as depicted for structure VII (BABA-yne, Fig. 26).

The general structure of the novel compounds claimed (Structure 4) include the following characteristics:

(1) The two polyamine backbones are either spermidine [*N*-(3-aminopropyl)-1,4-diaminobutane], *sym*-homospermidine [*N*-(4-aminobutyl)-1,4-diaminobutane] or *sym*-norspermidine [*N*-(3-aminopropyl)-1,3-diaminopropane].

(2) Each methylene group of the polyamine chain can be modified by methyl groups without compromising the ability of the inhibitor to interact with the polyamine transporter.

(3) Each primary amino group of the polyamine chains can be modified by methyl, ethyl or propyl groups without compromising the ability of the inhibitor to interact with the polyamine transporter.

(4) The central secondary amino groups of the two polyamine chains are connected via *N*-alkyl bonds by a linker (L) so that the resulting inhibitor has a $K_i \leq 20 \mu\text{M}$ (relative to spermine).

(5) The linker (L) can be of any nature or chain length, as long as the total final structure does not exceed 3,000. These molecules may in other embodiments be described as having a total mass of about 50 to about 2,500, or about between 500 to about 1,500, or about 1,000 as a total mass. By way of example, such linkers may comprise alkyl, aryl,

THIS PAGE BLANK (USPTO)

ether, thioether, disulfide, amide, phosphono, keto, amine and sulfonyl groups or a combination thereof.

The general design and use of dimers of spermidine, *sym*-homospermidine and *sym*-norspermidine corresponding to general Structure 4 comprise yet another aspect of the present invention.

For example, in some embodiments, these synthetic derivatives comprise a structure of a first polyamine chain and a second polyamine chain according to the structure.

Structure 4

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than two and less than five ($2 < x < 5$), y is greater than two and less than five ($2 < y < 5$), and L is a chemical structure (the linker) covalently connecting said second polyamine chain to said second chain through an alkyl bond, such as a α , ω , - diamine cross-linker.

In order to evaluate the effectiveness of dimeric triamines as polyamine transport inhibitors, we synthesized *N,N'*-bis(3-aminopropyl),*N,N'*-bis(4-aminobutyl)cystamine or BABAC (structure 1, FIG 25; FIG 31), and its thiol form *N*-(3-aminopropyl),*N*-(4-aminobutyl)cysteamine or AAC (FIG 31) according to Scheme 4 described above (FIG 30), using spermidine as a precursor polyamine. The ability of BABAC and AAC to inhibit the intracellular uptake of radio-labeled putrescine and spermidine in the ZR-75-1 human

breast cancer cell line was then determined according to standard published procedures (Lessard, et al. and Poulin, et al.). Briefly, ZR-75-1 cells were grown for four days in twenty-four well plates in RPMI 1640 medium supplemented with 10% fetal bovine serum, 1nM estradiol, 2mM L-glutamine, 1 mM sodium pyruvate, 15 mM Hepes and antibiotics, and specific uptake of [³H] putrescine, [³H]spermidine and [¹⁴C]spermine was measured as described (Lessard, et al.), using 20 μM and 3μM substrate, respectively. ZR-75-1 cells are a convenient system to assess the potential of polyamine transport inhibitors because they exhibit elevated polyamine uptake activity (Lessard, et al.).

As shown in FIG 32, BABAC was a potent inhibitor of putrescine, spermidine and spermine uptake in ZR-75-1 cells, with calculated apparent K_i values of 0.15 μM, 0.68 and 2.1 μM, respectively. Its thiol monomer AAC was a less potent transporter inhibitor (K_i = 0.54, 4.37 and 3.9 μM, respectively, as expected from the potentiating effect of dimerization on polyamine transport inhibition. Although the potency of BABAC to inhibit putrescine and spermidine uptake was only slightly lower than that of spermine (K_i of 0.0745 and 0.40 μM, respectively, for spermine), it was clearly greater than that of the dimeric spermine-like inhibitor DESC (FIG 31), which inhibited putrescine, spermidine and spermine uptake with apparent K_i values of 0.54, 5.6 and 7.5 μM, respectively. These data clearly indicate that dimerization of a shorter polyamine chain (i.e. spermidine relative to spermine) can still generate potent polyamine transport inhibitors, and that the nature of the linker L as well as its site of covalent attachment on the polyamine backbone can strongly influence the potency of the dimer to inhibit polyamine uptake. A comparison between the structures of DESC and BABAC suggests that a *N*-alkyl type of attachment leads to superior properties of polyamine transport inhibition than an amide linkage on a methylene group of the polyamine backbone, and that this effect dominates over the effect of elongating the polyamine chains.

EXAMPLE 11 **POLYAMINE TRANSPORT INHIBITION BY** **SYM-NORSPERMIDINE DIMERS**

To further evaluate the validity of the design of dimeric triamines as polyamine transport inhibitors, we have assessed the ability of a *sym*-norspermidine dimer, namely

THIS PAGE BLANK (USPTO)

N,N,N',N'-tetrakis(3-aminopropyl)-*p*-xylylenediamine (TADAX) (FIG 25), to inhibit polyamine uptake in ZR-75-1 cells.

TADAX (FIG 25) was synthesized according to the Scheme 2 described above (FIG 26). Briefly, into a solution of norspermidine (2.55 g) and diethylamine (8.0 mL) in chloroform (100 mL) was added trityl chloride (10.87 g) portionwise. After addition, stirring was continued for 24 h. The reaction mixture was washed with water and dried over anhydrous potassium carbonate. The solution was concentrated under reduced pressure and the residue was re-crystallized from dichloromethane-methanol to obtain *N',N'*-bis(trityl)norspermidine. ¹H NMR (300 MHz, CHCl₃) δ 2.26 (m, 12H, aromatic H), 7.12-7.30 (m, 18H, aromatic H), 2.36 (t, 4H, J = 8 Hz, 2 x CH₂N), 2.18 (t, 4H, J = 8 Hz, 2 x CH₂N), 1.66 (m, 6H, 2 x CH₂ and 2 x NHTr).

A mixture containing *N',N'*-bis(trityl)norspermidine (770 mg), α,α'-dibromo-*p*-xylene (166 mg), anhydrous Na₂CO₃ (573 mg), acetonitrile (45 ml) and DMF (3 drops) was refluxed under nitrogen atmosphere for 3 days. Then, the mixture was filtered while it was still hot and the filtered solid was washed thoroughly with water and dried to give *N,N,N',N'*-tetrakis(*N*-trityl-3-aminopropyl) *p*-xylylene diamine. ¹H NMR (300 MHz, CHCl₃) δ 7.24 (m, 24H, aromatic H), 6.92-7.34 (m, 36H, aromatic H), 3.42 (s, 4H, 2 X CH₂), 2.42 (m, 8H, 4 X CH₂N), 2.08 (m, 8H, 4 X CH₂N), 1.64 (m, 12H, 4 X CH₂ and 4 X NHTr).

N,N,N',N'-tetrakis(*N*-trityl-3-aminopropyl) *p*-xylylene diamine (374 mg) was suspended in a solution of HCl 6 M (20 mL) and the mixture was refluxed for 24 hours. The solid was removed by filtration and the aqueous phase concentrated to 2-3 mL by rotary evaporation. Addition of ethanol into the concentrated solution afforded the hexahydrochloride salt of *N,N,N',N'*-tetrakis(3-aminopropyl) *P*-xylylenediamine, or TADAX (FIG 25).

The ability of TADAX to inhibit [¹⁴C]spermine transport was next compared in ZR-75-1 human breast cancer cells using 3 μM substrate (FIG 32). In this assay, spermine has an apparent *K_m*=0.6 μM. It is clear that the *p*-xylylene norspermidine dimer TADAX (*K_i* = 1.5 μM) is a much more potent spermine transport inhibitor than the prototypic spermine dimer DESC (*K_i* = 17 μM), and was nearly as potent as the substrate spermine at interacting with the polyamine carrier in these cells. These data further demonstrate the

THIS PAGE BLANK (USPTO)

importance of the crosslinker **L** in the relative ability of triamine dimers to inhibit polyamine transport.

To further substantiate the usefulness of triamine dimers such as TADAX as transport inhibitors, the cytotoxicity of TADAX and its ability to serve a transported substrate for the polyamine carrier were then evaluated. As shown in FIG 34, TADAX was remarkably non-toxic to ZR-75-1 cells ($IC_{50} > 500 \mu M$), as compared to *sym*-norspermidine or the disulfide BABAC, which had lethal effects on ZR-75-1 cells with IC_{50} values of 6.4 and 17 μM , respectively. While the cytotoxicity of *sym*-norspermidine has been well documented (Bergeron and Seligshon, Komori and Ohsugi, Porter and Bergeron), a less pronounced, but yet significant cytotoxicity of DESC has been found using ZR-75-1 breast cancer cells. That cytotoxicity may well be related to the reactivity of the disulfide groups of DESC and BABAC with biological thiols and disulfides found in growth media and at the cell surface. Thus, despite the presence of four 3-aminopropyl groups on the TADAX backbone, and its two *sym*-norspermidine-derived moieties, it is remarkably inert toward biological functions. This is consistent with the fact that no detectable accumulation of the compound was found in ZR-75-1 cells even after a 6-hour incubation, as determined by ion pairing-reverse phase high-pressure liquid chromatography of cell extracts performed as described (Lessard, et al.) (data not shown). These data suggest that the very low cytotoxicity of TADAX is related to its lack of uptake by ZR-75-1 cells. Moreover, these properties are those expected from an impermeant, pure antagonist of polyamine transport such as DESC, thus supporting the potential usefulness of TADAX and similar triamine dimers to preempt polyamine uptake by tumor cells.

Synthesis of Embodiments

(1) **Unmethylated spermine analogs (FIG 17A):** N' , N' , N^8 , N'^2 -tetra-Boc-5-carboxyspermine (IV, FIG 12) is first prepared as described (88). If the linker is going to be amidated to the polyamine chain, the carboxyl group used as an acceptor is activated with cyanuric chloride (88), and conjugated with a *N*-mono-FMOC diaminoalkane of the desired length to generate the corresponding N' , N' , N^8 , N'^2 -tetra-Boc-spermine-5-*N*-(N' -FMOC-aminoalkyl) carboxamide (V, FIG 12). The FMOC group of the latter compound is removed with 20% piperidine/DMF, and the resulting N' , N' , N^8 , N'^2 -tetra-Boc-spermine-

THIS PAGE BLANK (USPTO)

5(*N*- ω -aminoalkyl) carboxamide (VI, FIG 12) is then reacted with the acid chloride form of *N'*, *N'*, *N*8, *N'*¹²-tetra-Boc-5-carboxyspermine (IV, FIG 12). The latter compound is then deprotected with HCl/CH₃COOH to obtain the corresponding *N'*, *N'*-bis(spermine-5-oyl)-diaminoalkane, the desired transport inhibitor (VII, FIG 12). These compounds are symbolized as BS compounds, and BS-3, BS-4, BS-5 and BS-6 correspond to the forms where the diaminoalkane linker is 1,3-diaminopropane, 1, 4-diaminobutane, 1, 5-diaminopentane and 1, 6-diaminohexane, respectively. If the spacer is going to be alkylated to the polyamine chain, the carboxyl group used as an acceptor in an amidation reaction is first reduced to an alcohol with LiAlH₄. After protecting the amine groups with carbobenzoxy (CBZ) groups, the alcohol is then converted to a bromide with PBr₃. The resulting CBX-protected spermine bromide is then reacted with a diamine spacer with a 2:1 stoichiometry to generate the CBZ-protected spermine dimer. This dimer is finally deprotected by catalytic hydrogenation with Pd/C (82) to generate the unmethylated spermine dimer (the transport inhibitor). If an ether linkage is desired, the alcohol obtained as above is then converted to an alkoxide with sodium metal, and then reacted with an alkyl dihalide (e.g. 1,3-diiodopropane) with a 2:1 stoichiometry to generate the CBZ-protected polyamine dimer, which is then deprotected as above to generate the unprotected polyamine dimer (the transport inhibitor). As an alternative precursor to ornithine, one may use instead 2-hydroxyputrescine, synthesized as described (83), and proceed with carboxyethylation and catalytic hydrogenation as in the route using ornithine as precursor, to obtain 6-hydroxyspermine. The four amino groups of the latter are protected with carbobenzoxy groups, and the alcohol is converted into an alkyl halide or alkoxide for subsequent reaction with the spacer as described above.

(2) **Methylated spermine analogs (FIG 17A):** For example, ornithine methylester (X, FIG 13) is synthesized as described (89) and is diamidated with two equivalents of 3-azidobutyric acid (XII, FIG 13) using DCC/OHBt (90) to generate *N'*, *N'*-bis (3-azidobutyryl)-ornithine methylester (XIII, FIG 13). The latter is then reduced using BH₃/THF (90) to obtain 1, 12-dimethylspermine-5 carbinol (XIV, FIG13). After protection of all four amino groups with Boc groups (XV, FIG 13), the carbinol group is activated with PBr₃ to generate 1, 12-dimethyl-*N'*, *N'*, *N'*, *N'*¹²-tetra (Boc)-5-bromomethyl spermine (XVI, FIG 14), and reacted with Fmoc-NH-(CH₂)_nNH₂ (where 3 ≤ n ≤ 6) to

THIS PAGE BLANK (USPTO)

generate the corresponding 1, 12-dimethyl- N^1 , N^4 , N^6 , N^{12} -tetra (Boc)-spermine-5 (N^{α} -methyl, N^{ω} -Fmoc-diaminoalkane) (XVII, FIG 14). After removing the Fmoc group with piperidine/dimethylformamide (XVIII, FIG 14), the free amino group of compound XVIII is alkylated with one equivalent of compound XVI to generate a N^{α} , N^{ω} -bis [1, 12-dimethyl- N^1 , N^4 , N^6 , N^{12} -tetra (Boc)-spermine]-5-methyl)-diaminoalkane (XIX, FIG 15). The latter compound is then deprotected with HCl/CH₃COOH to finally obtain the methylated spermine analog (BMS-3, BMS-4, BMS-5 and BMS-6), which are the desired transport inhibitors (XXa-d, FIG 15).

(3) **Unmethylated, *N*-alkylated spermine analogs (FIG 17B):** A symmetrical dimer that can be made where the linker (L) bridges two polyamine derivative chains through one of the innermost, secondary nitrogens of each polyamine chain.

(a) *N*-benzyl-1,3-diaminopropane (XXI, FIG 18) is first obtained by catalytic hydrogenation of 3-(benzylamino)propionitrile with Raney nickel as described (84).

(b) *N*-benzyl-1,3-diaminopropane is then *N*-alkylated with 3-bromobutyronitrile to generate N^1 -benzyl, N^3 -(3-cyanopropyl)-1,3-diaminopropane (XXII, FIG 18) (85).

(c) N^1 -benzyl, N^3 -(3-cyanopropyl)-1,3-diaminopropane is protected with a Boc group (86) to generate N^1 -benzyl, N^3 -Boc, N^3 -(3-cyanopropyl)-1,3-diaminopropane (XXIII, FIG 18)

(d) N^1 -benzyl, N^3 -Boc, N^3 -(3-cyanopropyl)-1,3-diaminopropane is reduced to N^1 -benzyl, *N*-Boc-spermidine (XXIV, FIG 18) by catalytic hydrogenation with Raney nickel (84).

(e) N^1 -benzyl, N^4 -Boc-spermidine is then cyanoethylated with acrylonitrile to generate N^1 -benzyl, N^4 -Boc, N^8 -cyanoethyl-spermidine, and reduced to N^1 -benzyl, N^4 -Boc-spermine by catalytic hydrogenation with Raney nickel (84) (XXV, FIG 18).

(f) The two free amino groups of N^1 -benzyl, N^4 -Boc-spermine are protected with CBZ groups as described (87) to generate N^1 -benzyl, N^4 -Boc, N^8 , N^{12} -di(CBZ)-spermine (XXVI, FIG 18).

THIS PAGE BLANK (USPTO)

(g) N^1 -benzyl, N^4 -Boc, N^8 , N^{12} -di(CBZ)-spermine is then deprotected to N^1 -benzyl, N^8 , N^{12} -di(CBZ)-spermine with trifluoroacetic acid as described (87) (XXVII, FIG 18).

(h) N^1 -benzyl, N^8 , N^{12} -di(CBZ)-spermine can then be cross-linked with an α,ω -dibromoalkane of the desired chain length to generate the corresponding bis(N^1 -benzyl, N^8 , N^{12} -di(CBZ)-spermine) dimer (XXVIII, FIG 19), which is then deprotected by catalytic hydrogenation with Pd/C (87) to generate the unmethylated, N -alkylated spermine dimer (the transport inhibitor) (XXIX, FIG 19).

(4) Methylated, N -alkylated spermine analogs (FIG 17B):

(a) The amino acid group of 3-aminobutyric acid is protected with Boc as described (89), and the resulting N -Boc-3-aminobutyric acid (XXX, FIG 20) is condensed with N -FMOC-1, 4-diaminobutane using DCC/OHBt (88) to obtain N^1 -(N -Boc-3-aminobutyl), N^4 -FMOC-1, 4-diaminobutane (XXXI, FIG 20).

(b) N^1 -(N -Boc-3-aminobutyl), N^4 -FMOC-1, 4-diaminobutane is then reduced to N^1 -Boc- N^8 -FMOC-1-methylspermidine with BH_3 /THF (88) (XXXII, FIG 20).

(c) Two equivalents of N^1 -Boc- N^8 -FMOC-1-methylspermidine are then N^4 -alkylated with one equivalent of the α, ω -diiodoalkane of the desired length to obtain the corresponding N^α, N^ω -bis (N -[N -Boc-3-amino, 3methylpropyl], N -[N -FMOC-4-aminobutyl])- α, ω -diaminoalkane (XXXIII, FIG 20).

(d) The FMOC groups of the resulting N^α, N^ω -bis (N -[N -Boc-3-amino, 3-methylpropyl], N -[N -FMOC-4-aminobutyl])- α,ω -diaminoalkane are then deprotected with 20% piperidine/DMF to yield the corresponding N^α, N^ω -bis (N -[N -Boc-3-amino,3-methylpropyl], N -[N -4-aminobutyl])- α,ω -diaminoalkane (XXXIV, FIG 20), which is then condensed with 3-azidobutyric acid, prepared as described (88), using DCC/OHBt, to generate the corresponding N^α, N^ω -bis(N -[N -Boc-3-amino,3-methylpropyl], N -[N -8-amino-5-aza-octanoyl])- α,ω -diaminoalkane.

(e) The N^α, N^ω -bis(N -[N -Boc-3-amino,3-methylpropyl], N -[N -8-amino-5-aza-octanoyl])- α, ω -diaminoalkane is then reduced to the corresponding N^α, N^ω -

THIS PAGE BLANK (USPTO)

bis(*N*-[*N*-Boc-3-amino,3-methylpropyl], *N*-[*N*-8-amino-5-aza-octyl])- α,ω -diaminoalkane with BH_3/THF (88) (XXXVII, FIG 21).

(f) The Boc groups of N^ω, N^ω -bis (*N*-[*N*-Boc-3-amino, 3-methylpropyl], *N*-[*N*-8-amino-5-aza-octyl])- α,ω -diaminoalkane are then removed with $\text{HCl}/\text{CH}_3\text{COOH}$ to generate the desired transport inhibitor, a N^ω, N^ω -bis (*N*-[3-amino, 3-methyl-propyl], *N*-[8-amino-5-aza-octyl])- α,ω -diaminoalkane (XXXVIII, FIG 21).

(5) 1,12-Dimethylated spermine dimers cross-linked through *N*-alkyl/C-alkyl attachments of the linker (FIG 17C):

Dimeric polyamine transport inhibitors of a different type can be generated by cross-linking one polyamine chain to a linker through a *N*-alkyl bond as in Examples 3 and 4 above, and the other polyamine chain via a C-linked anchor lying between the two innermost secondary amino groups as in Examples 1 and 2 above. Such compounds (as terminal C-methylated spermine analogs) can be obtained as follows:

(a) N^1 -Boc- N^8 -FMOC-1-methylspermidine (XXXII, FIG 20), obtained as described above (Example 4, steps a to b), is N^4 -alkylated using an ω -bromoalkylphthalimide of the desired length as described (92), to generate the corresponding N^1 -Boc, N^4 -alkylphthalimide, N^8 -FMOC-1-methylspermidine (XXXIX, FIG 22).

(b) The phthalimide group of N^1 -Boc, N^4 -alkylphthalimide, N^8 -FMOC-1-methylspermidine is removed with hydrazine in EtOH (88, 90) to generate the corresponding N^1 -Boc, N^4 -(ω -aminoalkyl), N^8 -FMOC-1-methylspermidine (XL, FIG 22).

(c) The free amino group of N^1 -Boc, N^4 -(ω -aminoalkyl), N^8 -FMOC-1-methylspermidine is then alkylated with N^1, N^4, N^8, N^{12} -tetra (Boc)-1, 12-dimethyl-5-bromomethylspermine prepared as described in Example 2 (XVI, FIG 14) to obtain the corresponding N^ω ([*N*-Boc-3-amino, 3-methylpropyl], *N*-[*N*-FMOC-4-aminobutyl]), N^ω -[5-(N^1, N^4, N^8, N^{12} -tetra(Boc)-spermine)-methyl] α,ω -diaminoalkane (XLI, FIG 22).

THIS PAGE BLANK (USPTO)

(d) The Fmoc group of $N^{\omega}([N'-\text{Boc-3-amino, 3-methylpropyl}], N-[N'-\text{Fmoc-4-aminobutyl}])$, $N^{\omega}-[5-(N^1, N^4, N^8, N^{12}\text{-tetra (Boc)-spermine)-methyl}]\alpha, \omega$ -diaminoalkane is then removed with 20% piperidine/DMF, and the resulting $N^{\omega}([N'-\text{Boc-3-amino, 3-methylpropyl}], N-[4\text{-aminobutyl}])$, $N^{\omega}-[5-(N^1, N^4, N^8, N^{12}\text{-tetra (Boc)-spermine)-methyl}]\alpha, \omega$ -diaminoalkane (XLII, FIG 23) is condensed with 3-azidobutyric acid (XXX, FIG 21) as in Example 4 (step d) above, to generate the corresponding $N^{\omega}([N'-\text{Boc-3-amino, 3-methylpropyl}], N-[8\text{-amino-5-aza-octanoyl}])$, $N^{\omega}-[5-(N^1, N^4, N^8, N^{12}\text{-tetra (Boc)-spermine)-methyl}]\alpha, \omega$ -diaminoalkane (XLIII, FIG 23).

(e) $N^{\omega}(N-[N'-\text{Boc-3-methylpropyl}], N-[8\text{-amino-5-aza-octanoyl}])$, $N^{\omega}-[5-(N^1, N^4, N^8, N^{12}\text{-tetra (Boc)-spermine)-methyl}]\alpha, \omega$ -diaminoalkane is then reduced to $N^{\omega}(N-[N'-\text{Boc-3-amino, 3-methylpropyl}], N-[8\text{-amino-5-aza-octyl}])$, $N^{\omega}-[5-(N^1, N^4, N^8, N^{12}\text{-tetra (Boc)-spermine)-methyl}]\alpha, \omega$ -diaminoalkane (XLIV, FIG 24) with BH_3/THF as in Example 4 (step e) above, and the Boc groups of the resulting compound are removed with $\text{HCl}/\text{CH}_3\text{COOH}$ to generate the corresponding $N^{\omega}(N-[N'-[3\text{-amino, 3-methyl-propyl}], N-[8\text{-amino-5-aza-octyl}])$, $N^{\omega}-[5-(1, 12\text{-dimethyl-spermine)-methyl}]\alpha, \omega$ -diaminoalkane (XLV, FIG 24), which is the desired polyamine transport inhibitor.

(6) **SCHEME 1 (FIG 27): synthesis of *sym*-norspermidine dimers using total cyanoethylation of aliphatic or aromatic diamines**

This scheme is used to prepare symmetrical dimers of *sym*-norspermidine by Michael addition via total cyanoethylation of hydrochloride salts of aliphatic or aromatic α, ω -diamines. This route is the simplest one to generate polyamine dimers since no amine protection is necessary. The diamine hydrochloride of the desired nature and chain length (VIII, FIG 27) to be used as a crosslinker is stirred with a 4-fold excess of acrylonitrile in the presence of triethylamine (Et_3N) in aqueous solution, yielding a N, N, N', N' -tetrakis(cyanoethyl)- α, ω -diamine (IX, FIG 27). Cyanoethyl groups are then reduced with NaBH_4 in the presence of methanolic CoCl_2 as a reducing agent, resulting in the formation of a *sym*-norspermidine dimer (X, FIG 27) with the desired linker L. The compound is

THIS PAGE BLANK (USPTO)

obtained as its hexahydrochloride salt after alkaline extraction with $\text{CHCl}_3/\text{Na}_2\text{CO}_3$ and solubilization in HCl.

Various linkers can be used according to that scheme, including aliphatic α,ω -diaminoalkanes (preferably with a chain length greater than two and less than ten) which may incorporate one double bond in a *cis* or *trans* configuration, or one triple bond, and aromatic diamines where the amino groups are present as aminoalkyl substituents at two different positions of the aromatic cycle, such as the *para* configuration shown in FIG 27.

(7) SCHEME 2 (FIG 28): synthesis of spermidine, *sym*-homospermidine and *sym*-norspermidine dimers using direct alkylation of the central secondary amino group with a dibromoalkene or dibromoarene

Spermidine, *sym*-homospermidine and *sym*-norspermidine dimers can be prepared by protecting the primary amino groups of the precursor triamine with trityl groups, and directly alkylating the secondary amino group of the triamine with a dibromoalkene, a dibromoalkyne or a dibromoarene with the desired crosslinking carbon chain (Zang and Sadler). For this purpose, the primary amine groups of the triamine XI (FIG 28) are reacted with trityl chloride in the presence of diethylamine in CHCl_3 to obtain the N^α, N^ω -bis(trityl) polyamine chain XII (FIG 28). Two equivalents of the latter compound are then refluxed with the alkyl or aryl dibromide form of the desired linker L to generate the trityl-protected form of the desired triamine dimer (XIII, FIG 28). The trityl groups of this dimer are then removed by refluxing with 6 N HCL to obtain the hexahydrochloride salt of the polyamine transport inhibitor XIV (FIG 28). Dibromoalkanes tend to form heterocyclic by-products with the triamine precursor, and therefore the present scheme is chiefly used as a simply synthetic method to generate dimeric triamine-derived polyamine transport inhibitors with unsaturated or aromatic linkers.

(8) SCHEME 3 (FIG 29): synthesis of spermidine *sym*-homospermidine and *sym*-norspermidine dimers by amidation with an acyl chloride followed by reduction of the amide groups

An alternative, even more versatile approach to generate spermidine, *sym*-homospermidine and *sym*-norspermidine dimers as polyamine transport inhibitors is to

THIS PAGE BLANK (USPTO)

crosslink the secondary amino groups of the triamine chains, protected with trityl groups as in Scheme 2 (**XII**, FIG 28 and FIG 29), with the α,ω -diacyl chloride form of the desired linker **L**, and then reduce the amide bonds of the resulting molecules. For this purpose, two equivalents of the trityl-protected triamine precursor **XII** are reacted with the diacyl chloride of choice in the presence of triethylamine/ CHCl_3 to obtain the corresponding diamide form of a trityl-protected triamminen dimer **XV** (FIG 29). The diamide is then reduced to its *N*-alkyl form with LiAlH_4 in dry THF under nitrogen to obtain the trityl-protected form of the triamine dimer (**XIII**, FIG 28 and FIG 29). The primary amine groups are then freed with 6 N HCl as in Scheme 2 to generate the desired dimeric polyamine transport inhibitor **XIV** (FIG 28 and FIG 29).

This scheme is superior to Scheme 2 for dimerizing triamine molecules with aliphatic linkers of the general structure $-(\text{CH}_2)_n-$, which tend to form heterocycles with the polyamine chain when reacted in their dihalide form.

(9) SCHEME 4 (FIG 30): synthesis of dimeric spermidine, *sym*-homospermidine and *sym*-norspermidine disulfides

Synthesis of useful dimeric polyamine transport inhibitors is not limited to those containing aliphatic or aromatic carbon chains. Triamines can be dimerized via *N*-alkyl bonds with a linker **L** containing a disulfide bond, generating polyamine transport inhibitors with even higher potency than DESC, which is a dimeric spermine disulfide cross-linked through amide bonds with position C5 of each spermine skeleton. The following scheme allows the synthesis of dimeric triamines cross-linked via *N*-alkyl bonds with a diethyl disulfide chain.

The primary amino groups of the desired triamine **XI** (FIG 28 and FIG 30) are first protected with ethyl trifluoroacetate in aqueous acetonitrile to obtain the bis-trifluoroacetyl-protected triamine **XVI** (FIG 30). The latter compound is then reacted with one equivalent with ethylene sulfide (Cohen, et al.), 1.2 equivalent of diisopropylethylamine (Hunig's base) and 0.1 equivalent of CuCl in dry acetonitrile in the presence of 2,2'-dithiobis(benzothiazole) to catalyze the formation of the disulfide from an intermediate thiol (Brzezinska and Ternay), to generate the trifluoroacetyl-protected triamine dimeric disulfide **XVII** (FIG 30). Trifluoroacetyl groups are removed from the

THIS PAGE BLANK (USPTO)

latter compound using MeOH/NH₃ (4:1) at pH 11, yielding the free dimeric triamine disulfide **XVIII** (FIG 30). The latter disulfide can be further reduced to its free thiol **XIX** (FIG 30) with either dithiothreitol or tris(carboxyethyl)phosphine (**Burns, et al.**).

THIS PAGE BLANK (USPTO)

CLAIMSWHAT IS CLAIMED IS:

1. A synthetic derivative of an original polyamine, wherein a carbon atom of said original polyamine comprises an amide group, said synthetic derivative inhibiting the cellular uptake of a natural polyamine by specifically binding a cellular transporter for said natural polyamine.

2. A synthetic derivative according to claim 1, wherein the carbon to which said amido group is located between two internal nitrogen atoms of said original polyamine.

3. A synthetic derivative according to claim 2 which comprises a dimer of said original polyamine, the monomers of said dimer being linked together by a spacer side chain anchored to the amido group of each monomer.

4. A synthetic derivative according to claim 3, wherein the original polyamine is selected from the group consisting of putrescine, spermidine and spermine.

5. A synthetic derivative according to claim 4, wherein the original polyamine is spermine.

6. A synthetic derivative according to claim 2, wherein said synthetic derivative has the following general formula:

THIS PAGE BLANK (USPTO)

in which R_1 and R'_1 independently represent a hydrogen atom or an alkyl group having 1 to 3 carbon atoms, R_2 , R'_2 , or R_3 and R'_3 independently represent a hydrogen atom or a methyl group, w and z independently represent an integer of 3 or 4, x represents an integer from 0 to n , y represents an integer from 0 to n , n represents an integer from 3 to 6, the sum of x and y equals n , and L represents a hydrogen atom or a molecule which cannot be captured by said natural polyamine transporter.

7. A synthetic derivative according to claim 3, wherein said monomer has the following general formula:

in which R_1 and R'_1 independently represent a hydrogen atom or an alkyl group having 1 to 3 carbon atoms, R_2 , R'_2 , or R_3 and R'_3 independently represent a hydrogen atom or a methyl group, w and z independently represent an integer of 3 or 4, x represents an integer from 0 to n , y represents an integer from 0 to n , n represents an integer from 3 to 6, the sum of x and y equals n , and L is the spacer side chain that comprises a linear hydrocarbon-containing backbone of 3 to 8 atoms.

8. A derivative according to claim 7, wherein said backbone comprises sulfur, oxygen, phosphorus or nitrogen.

9. A derivative according to claim 8, wherein $w=3$, $z=3$, $x=0$ and $y=3$.

10. A derivative according to claim 7, wherein $w=3$, $z=3$, $x=0$ and $y=3$.

11. A derivative according to claim 8, wherein $w=3$, $z=3$, $x=0$ and $y=4$.

THIS PAGE BLANK (USPTO)

12. A derivative according to claim 9, wherein the hydrocarbon-containing backbone comprises a disulfide bridge.

13. A derivative according to claim 9, which is *N*(2-mercaptoethyl)spermine-5-carboxamide.

14. A derivative according to claim 9, which is *N*(2,2'-dithio(ethyl, 1'-aminoethyl)spermine-5-carboxamide).

15. A derivative according to claim 12 which is 2,2'-dithiobis(*N*-ethylspermine-5-carboxamide).

16. The use of a synthetic derivative according to any one of claims 1 to 15 for inhibiting the activity of a natural polyamine transporter comprising the step of contacting said transporter with an inhibitory effective amount of said synthetic derivative.

17. The use according to claim 16, which results in the control or the treatment of disorders involving unrestrained cell proliferation and/or differentiation where control of polyamine transport is required, when used in combination with an inhibitor of polyamine synthesis.

18. The use according to claim 16 wherein the inhibitor of a polyamine synthesis is DFMO.

19. The use of the synthetic derivative of any one of claims 1, 2, 6, 9, 13 and 14 as a marker for a polyamine transporter, wherein said synthetic derivative comprises a detectable label having affinity for a polyamine transporter and wherein said use comprises the steps of labeling said synthetic derivative to provide a labeled synthetic derivative, binding said labeled synthetic derivative to a polyamine transporter, and employing said labeled synthetic derivative bound to a polyamine transporter as a marker for the detection of a polyamine transporter.

THIS PAGE BLANK (USPTO)

20. The use according to claim 19 which results in the diagnosis of a disorder involving unrestrained cell proliferation and/or differentiation where control of polyamine transport is required.

21. A pharmaceutical composition for treating disorders wherein control of polyamine transport is required, comprising a synthetic derivative according to any one of claims 1 to 15 in combination with an acceptable pharmaceutical carrier.

22. A pharmaceutical composition according to claim 21, which further comprises an inhibitor of polyamine synthesis.

23. A pharmaceutical composition according to claim 22, wherein said inhibitor of polyamine synthesis is a α -difluoromethylornithine.

24. A synthetic derivative of a polyamine comprising

wherein R_1 or R_2 and R_{18} or R_{19} is methyl, R_3 through R_{17} is H or methyl, and L is a linker comprising a chemical entity covalently attached to said polyamine and capable of modifying the membrane permeability of a polyamine analog.

25. The derivative of claim 24 wherein the L is a α,ω -diamine cross-linker.

26. The synthetic derivative of Claim 25 wherein at least one of R_1 and R_2 and one of R_{18} and R_{19} are methyl groups.

THIS PAGE BLANK (USPTO)

27. A synthetic derivative of a polyamine having a structure:

wherein n is 3, 4, 5 or 6.

28. The synthetic derivative of claim 27 wherein n is 3.

29. The synthetic derivative of claim 27 wherein n is 4.

30. The synthetic derivative of claim 27 wherein n is 5.

31. The synthetic derivative of claim 27 wherein n is 6.

32. A synthetic derivative of a polyamine comprising Structure 1:

THIS PAGE BLANK (USPTO)

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than two and less than five ($2 < x < 5$), and the sum of $y+z$ is greater than or equal to 6 ($2 \leq y + z \leq 6$), R_3 is an alkyl, amide, keto, ether, thioether, phosphono or sulfonyl group; and L is a linker as defined in claim 24.

33. The synthetic derivative of claim 32 wherein x is 3, R_1 is hydrogen, R_2 is a methyl (CH_3) group for the carbon atom located next to each $\text{NH}-R_1$ group, and is a hydrogen atom for all other carbons, $y + z = 3$, and L is $-\text{CH}_2-\text{HN}(\text{CH}_2)_n\text{NH}-\text{CH}_2-$, where $n = 3, 4, 5$ or 6 .

34. A synthetic derivative of a polyamine comprising Structure 2:

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than two and less than five ($2 < x < 5$), w is greater than 2 and less than 8 ($2 < w < 8$) and L is a linker as defined in claim 24.

35. The synthetic derivative of claim 34 wherein $x=3$, R_1 is a hydrogen atom, R_2 is a methyl (CH_3) group for the carbon atom located next to each $\text{NH}-R_1$ group, and is a hydrogen atom for all other carbons and $w = 4$.

THIS PAGE BLANK (USPTO)

36. A synthetic derivative of a polyamine comprising Structure 3:

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than two and less than five ($2 < x < 5$), w is greater than 2 and less than 8 ($2 < w < 8$), and R_3 is an alkyl, amide, keto, ether, thioether, phosphono or sulfonyl group; the sum of $y+z$ is greater than or equal to 2 and less than or equal to 6 ($2 \leq y + z \leq 6$); and L is a linker as defined in claim 24.

37. The synthetic derivative of claim 35 wherein L is an aliphatic chain with a length of 2 to about 14 carbon atoms.

38. A synthetic derivative comprising a structure of a first polyamine chain and a second polyamine chain having a structure:

THIS PAGE BLANK (USPTO)

wherein R_1 is H, methyl, ethyl or propyl, R_2 is H or methyl, x is greater than 2 and less than 5, y is greater than 2 and less than 5, and L is a chemical linker covalently connecting said first polyamine chain to said second polyamine chain.

5 39. The synthetic derivative of claim 38, wherein the chemical linker is a α, ω - diamine cross-linker.

40. The synthetic derivative of claim 38 wherein the chemical linker is further defined as an alkyl chemical linker.

10

41. The synthetic derivative of claim 38, when R_1 is H, X is 3 or 4, Y is 3 or 4, and $X + Y$ is greater than 5 and less than 9.

15

42. The synthetic derivative of claim 38 wherein L is an aliphatic carbon chain having a structure $C-(CH_2)_\eta$, and η is greater than 2 and less than 10.

43. The synthetic derivative of claim 38 when L is xylene.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 98/ 07806

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 16-20
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claim(s) 16-20
is(are) directed to a method of treatment of the human/animal
body, the search has been carried out and based on the alleged
effects of the compound/composition.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such
an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see further information sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all
searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment
of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report
covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is
restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-23, 27-31

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

1. Claims: 1-23,27-31

Polyamine derivatives having an amide group as well as their
use

2. Claims: 24-26,32-43

Polyamine derivatives with linker having no amide group
